independent functional variable EMG, and the dependent functional variable lip. One particular issue is the appropriate choice of the time lag δ the length of time within the model that neural activity can continue to affect movement. Models for increasing values of δ correspond to nested linear models, and in this case a study of the amount of variation explained demonstrates that there is little effect beyond a lag of about half a second.

An important theoretical and practical issue is the necessity or otherwise of incorporating some form of smoothing or regularization into a functional analog of a classical multivariate procedure. In principal components analysis, the principal components, such as those displayed in Figure 7, are smoothed or regularized and in some procedures, such as canonical correlation analysis (see also Multivariate Analysis: Discrete Variables, Overview) or certain types of linear modeling for the lip/EMG data, regularization is necessary to give any meaningful results at all; see Leurgans et al., (1993), and Ramsay and Silverman (1997: Chapters 11 and 12).

Modeling with Derivatives: A Central Theme

It is the smoothness of the processes generating functional data that differentiates this type of data from more classical multivariate observations. This smoothness means that we can work with the information in the derivatives of functions or images. We looked at acceleration in the growth data, found something interesting in the joint variation of the velocity and acceleration of nondurable goods production, and used derivatives to define roughness penalties; see Ramsay and Silverman (1997: Chapter 4) for the weather data.

We may also use derivatives to construct models for data. Such models are called differential equations, and are part of the standard model-building toolkit in the natural sciences and engineering. Differential equation models are often called dynamic models, since they are especially effective at representing processes unfolding in time. Ramsay (2000) developed a linear differential equation for handwriting involving velocity, acceleration, and the third derivative of the tip of the pen. Figure 8 shows a sequence of pen positions during the writing of the word 'statistics' in Mandarin, and also shows as a solid line its approximation on the basis of the dynamic equation estimated from 50 such samples of Chinese script. The equation not only captured the essential features of this particular sample, but was also able to model a fair amount of the sample-to-sample variation as well. And, finally, it also provided an excellent account of the velocity, acceleration, and jerk functions at the same time. Ramsay and

Figure 8 Observations of the tip of the pen while writing the word 'statistics' in Mandarin. Notes: Dots indicate 2400 observations; solid line is an approximation based on a second-order linear differential equation.

Silverman (1997: Chapters 13 and 14) take up this topic of dynamic modeling with functional data, including an account of a technique called 'principal differential analysis,' developed by Ramsay (1995).

Relationships with Other Branches of Statistics

Of course, statisticians have been exploring curves for a very long time, and there are many older statistical methodologies that can continue to inform and enrich an FDA. First of all, FDA usually begins with some kind of nonparametric regression (e.g., see also Exploratory Data Analysis: Univariate Methods) in order to replace discrete and possibly noisy curve values by smooth, continuous functions. Density estimation also involves data smoothing. Typically, time series analysis (Brillinger, 1981; Box and Jenkins, 1994) considers long sequences of curve values corresponding to equally spaced time values that are more or less stationary; that is, the data show little overall trend, and the covariance among neighboring values does not change much from one time region to another. However, methods for nonstationary processes are also under active development, and there are strong structural links between times series methods such as state-space modeling and FDA methods such as smoothing. Longitudinal data analysis or multilevel modeling (Diggle et al., 1994; Searle et al., 1992) usually looks at shorter sequences of curve values sampled over many cases, and studies the structure of between- and within-curve variation. It seems likely that this field and FDA will merge in a number of useful ways. Multivariate statistics has many methods developed specifically for functional data that have preceded FDA, but which have not explicitly exploited the smoothness of functional data or made other uses of derivatives (see also Probability Density Estimation; Longitudinal Data: Event–History Analysis in Discrete Time; Multivariate Analysis: Discrete Variables, Overview).

Conclusion

By the smoothness of a functional observation we have meant the possibility that one or more derivatives, such as velocity or acceleration, may be examined or used in the modeling process. Otherwise, FDA makes only minimal assumptions about the structure of variation within and between curves. We have seen, however, that teasing apart amplitude and phase variation is a central issue, and one that has largely been ignored until recently. Certain types of models considered to be fairly routine and well understood in multivariate statistics, such as linear regression, have many more variants in the functional domain, and are being researched actively. Software for FDA is also being developed, and it is likely that FDA will soon be considered as a routine item in a data analyst's black bag of instruments and nostrums. Further information on FDA and related issues may be obtained in Pinheiro and Bates (2000), Ramsay and Silverman (1997), and Simonoff (1996).

Functional Explanation: Philosophical Aspects

Graham Frank Macdonald, University of Canterbury, Christchurch, New Zealand; and University of Manchester, Manchester, UK

Abstract

In the philosophy of biology and philosophy of psychology and social science there has been considerable controversy over what the correct account of functional explanation is, with the contending accounts splitting into two main camps. Both camps agree that functional explanation is dependent on an account of functions, but disagree on the account they give. Within evolutionary biology, the favored view is that functions emerge over time as a consequence of evolutionary processes, a feature of an organism only having a function if it has a suitable history. This version is aptly called the historical, or etiological, view of functions. The opposed view is that the operation of a system can be analyzed to reveal how parts of the system enable the system to behave in a certain manner. This version is best known as a 'systems' or 'Cummins'' account of functions and functional explanation. This article examines both these views. In addition, the controversy over what it is that functional explanations explain will be outlined. Along the way, the notion of 'malfunction' will be defined, the criticisms of panadaptationism scrutinized, functional explanation of novel features or behavior defended, and the claims of dispositional or 'virtual' selection inspected.

Functional explanation has received a great deal of philosophical attention in recent years, partly as a consequence of a surge of interest in the philosophy of biology, and partly as a consequence of attempts to make functions and functional explanation central to issues in the philosophy of psychology. In both these areas, there has been some controversy over what the correct account of functional explanation is, with the contending accounts splitting into two main camps. Both camps agree that functional explanation is dependent on an account of functions, but disagree on what the correct account is. Within evolutionary biology, the favored view is that functions emerge over time as a consequence of evolutionary processes, so a certain feature of an organism will only have a function if it has a suitable history. The opposed view is that the operation of a system can be analyzed into the way in which parts of the system function to make the system behave in that manner. This version has many names, but is perhaps best known as a 'systems' or 'Cummins'' account of functions and functional explanation, but it has also been called 'causal-role' functionalism. In what follows, both these views will be examined; in addition, the controversy over what it is that functional explanations explain will be outlined.

Functions and Systems

The 'systems' account of functions takes as its starting point the fact of (biological) complexity and proposes to understand the complex functioning of a biological entity (or system) in terms of the working of its parts. The fact of complexity suggests that the systems are goal directed, and if this is taken for granted one can recover what is distinctive of many explanations in biology, that they invariably cite the effects of causes as explaining why the cause is there. It does this by specifying how a part of the system operates in the production of the aimed-at goal.

The best known account of how such an explanation operates is given by Cummins (1975, 1983). He distinguishes explanation of changes, which is done by 'transition' theories, from explanation of properties. Transition theories are suitable for explaining 'What caused S to acquire P?' whereas a property theory explains what it is for S to instantiate P. This is best done by constructing an analysis of S, such an analysis adverting to the properties of S's components and their organization. So the kinetic theory of gases explains what it is for a gas to have temperature via an account of the properties of the molecules contained within the gas. Cummins calls the analysis of such a system compositional analysis: the analysis of a dispositional property being called functional analysis. The general claim is that in science the ascription of a function to something is to specify a capacity, such a capacity being identified by its role in enabling a system to operate in a certain manner. Thus, in biology, the capacities of an organism are explained by analyzing them into a number of systems (circulatory, digestive, etc.), such systems having a particular task to perform. How these tasks get performed is in turn explained by functional analysis, such an analysis citing the capacities of parts of these systems. Such capacities are the functions of the parts, so we get the Cummins-style definition of function:

> X functions as an F in s (or: the function of X in s is to F) relative to an analytical account A of s's capacity to G just in case X is capable of F-ing in s and A appropriately and adequately accounts for s's capacity to G by, in part, appealing to the capacity of X to F in s (Cummins, 1975, p. 762).

This account clearly does not restrict the attribution of functions to biological organisms; one can recognize the attribution of this type of function to parts of societies within sociological and anthropological functionalism. Here, the system was seen as a society or culture, and the parts were the subsocietal structures or the recurrent patterns of behavior, the function of which was to maintain the structural continuity of the whole. The fact that this account of functionality is applicable to any system has given rise to two criticisms of this approach, one seeing a problem in how to specify non-arbitrarily which behavior or capacity of the containing system

is relevant for the functional analysis to analyze, the second seeing a difficulty in producing a sufficiently determinate notion of a 'system' for which a functional analysis is appropriate. The problem is that the choice of both a capacity and a system may seem to depend upon our decisions in a way that could make the functional analysis of any capacity or system seem justifiable. The pertinent question here concerns the explanatory gain made by the appeal to functional analysis. There seems to be no explanatory payoff in some cases where functional analysis may be applied. Take the 'system' that is my study, which includes as parts various items of furniture, books, and me. The property of the room that one wants explained is its temperature. Say my presence in the study raises the temperature of the room by 1/2 a degree. One does not gain any insight into the working of this system by attributing to me the function of enabling the room (the system) attain its present temperature.

Cummins was aware of this trivialization of functional analysis, and suggested constraints on the choice of a system and capacity that could be analyzed illuminatingly. One problem with the above analysis is that the capacity to be explained via functional analysis, the temperature of the room, is similar in kind and complexity to the property doing the explaining, my body temperature. One only gets an explanatory payoff when the analyzing property is both less complicated than, and different in kind from, the analysandum. This suggests the third constraint imposed by Cummins: one is not going to get a less sophisticated property doing all the explanatory work in showing how a complex system operates. The analysis will have to appeal to the operation of component parts and their properties, their combined action producing the complex behavior of the system. It is through the organization of interdependent parts that simplicity generates complexity, and functional analysis succeeds when it shows how this can be achieved.

The choice of system and capacity to be analyzed, then, is constrained: functional analysis will be applied fruitfully only to a complex system whose behavior is produced by the action of simpler but well-organized parts. It is unsurprising, then, that the systems most often favored as exemplars of systems suitable for functional analysis are those that have been designed. The interdependence of the parts of such systems is often attained by careful planning. The second theory of functions that will now be examined focuses on this 'design' aspect of the systems to whose parts functions can be aptly attributed.

Functions and Selection

It is the improbability of complex systems existing by chance that suggests that such systems are generated by design, and so have parts that function so as to produce the intended behavior of the system. With artifacts, it is easy to see how functionality can be ascribed: the complex system is designed intentionally to have the capacity to produce certain effects, and the parts are chosen for their ability to contribute toward that goal. They are selected for that task. This type of functionality is derived from intentionality. The achievement of Darwin and Wallace was to provide a nonintentional explanation of how such complexity could originate, and they did this via the theory of natural selection. The major strength of the historical account of functions is that it ties attribution of functions to 'design' by natural (nonintentional) selection. The essential features of this account are dependent upon the idea that to attribute a function to an item is to say that the item has that feature or behavior because it has a certain history: in the past that feature produced certain consequences, those consequences themselves having the effect of reproducing items with that feature. It is this latter aspect that makes the account teleological. One can say that the item has the relevant property in order to produce those consequences. It is because of (some of) its effects that the item with this capacity is selected for. What the theory of natural selection does is make respectable the apparent purposefulness of the 'in order to.' It does this by showing how environmental pressures on variable items can produce varied reproduction of those items; those items with certain features will become more prevalent because those features have typical effects on the reproductive capacity of the items that bear them.

The long neck of the giraffe, to take a standard example, is an adaptation and has the function of enabling giraffes to eat the leaves at the top of tall trees. On the historical account, this capacity is the function of the long neck because previous giraffes whose genes produced longer necks than their contemporaries were better producers of offspring, and were so just because of the advantage conferred on those giraffes in the food wars. This results, in the long run, in more long-necked giraffes, until the giraffe is a long-necked species. Put as briefly and generally as possible, the etiological account says that functionality arises because some variants within a group (a mutant gene, for example) have (or produce) novel features with capacities that are favorable to their possessors' ability to reproduce (i.e., more favorable than the nonpossession of those features by the other members of the group). Such features are transmitted to their descendants, proliferating within the group in the process. The feature of the organism will then, and only then, has as its function the exercise of the favorable capacity.

As with Cummins-style functions, this account of functionality is very general. It applies not just to biological entities, but to all items that have the required characteristics of

1. variation in the characteristics of members of the population,
2. which causes different rates of production, and
3. which is inherited. (Godfrey-Smith, 2007: p. 515)

Selection cannot take place if there is no initial variation; the same selection forces operating on a homogenous population will have no effect. For a cause to be there in order to produce certain effects it must also be the case that instances of properties with those causal powers have been selected in the past because they produced those effects. The selection process requires that the causal property interact with salient features of the environment in such a way that other items without that property are seen to 'suffer' some loss as a consequence of their nonpossession of the property. Finally, it is because the favored properties are transmitted to descendants of the items having those features that the present items have these properties. Then it can be said that the property is, or was functional, its

function being to produce those types of effects that lead to its ancestors reproducing items with the property in question.

As the giraffe example indicates, it is in its forging a connection between function and adaptation that the strength of this account resides. Adaptations are produced historically via the operation of natural selection, so they are functional. A creature may have a feature that renders it 'adapted' to its environment because it so happens that that feature will help it flourish in that environment, but such a feature, lacking the relevant selectionist history, will be adaptive for the creature, but not an adaptation. The historical (etiological) theory of functions claims that it is because adaptations are selected, not accidental, features of organisms that we are entitled to the use of functional explanation.

The historical and systems account of functions are not necessarily competitors. It has been seen that the systems for which functional analysis is appropriate are complex, with the analysis proceeding by showing how the operation of simpler, interdependent parts can produce the relevant capacity of the system. Such systems, it can be claimed, come into being either by intention or by selection, so functional analysis will be appropriately applied in just those cases where some design-mechanism is operating. On this view, functional analysis is an accessory to the historical theory of functions. There are, however, two aspects of the historical conception that render it significantly different from the systems version. The first is a consequence of what has been suggested above: it is probable that complex systems are generated by some design process, but it is not impossible for such a system to emerge by chance. For such a system, a functional analysis would still be appropriate, but the historical version of functions would disallow the attribution of any function to the system or its parts, these not having the appropriate history. Second, the historical theory has the ability to include malfunctions within its purview. On the systems account, if a part 'functions' so as to produce a system with a different capacity from that expected, that part cannot be said to be malfunctioning. A functional analysis will proceed as usual, with the new capacity being analyzed, and the analysis showing just how it is produced given the nature of the contained parts, and their causal powers. On the historical conception, given a suitable account of reproduction, one can allow for mistakes to be made in the reproducing process, so that the items that are considered to be descendants of some common ancestor need not be perfect copies of that ancestor, and in particular may not have the causal powers for which items of that type have been selected previously. The item may then not do what it is supposed to do – it may malfunction. To appreciate this better, and to make manifest the power of the explanations that the historical theory makes available, that theory needs to be fleshed out in more detail.

Elaborations: Malfunction, Novelty Proper and Actual Domains

Malfunction

An essential aspect of the historical account is that a function results from selection operating over a period of time on items that are descended from each other. What is it to be descended in the relevant sense? Initially one may think in terms of copying, one item being a descendant of another if it is an exact copy of the former, and is so as a result of some lawlike process that ensures that such a replica is forthcoming. This is too strict a definition: for one thing, it would be impossible to provide a decent conception of a malfunctioning device if all descendants had to be exact copies of their ancestors. A malfunction involves some mistake, so a device that malfunctions will not be an exact copy of a properly functioning device. One has to allow for an item being a descendant of another even though the copying process is not perfect. One way of making what is involved more precise is due to Millikan (1984, 1993), and it goes like this: individual A is a reproduction of individual B if and only if B has some determinate properties in common with A, and this correlation of properties can be explained by a natural law operating in that environment. These common properties are the reproductively established properties of B, and the devices sharing these properties form reproductively established families (refs). (Only first-order refs reproduce in this manner. Higher order refs (horefs) are produced by first-order refs. My and my ancestors' two-leggedness is the result of common genes, such genes being first-order refs. They have certain properties in common, this being ensured by the laws of genetic inheritance.) Direct proper functions are functions of devices that are members of refs or horefs.

So how do we get malfunctioning members of refs or horefs? Millikan suggests that a malfunctioning member of a ref can be produced provided it has been produced by a device the proper function of which is to produce members of the ref in question, that it is in some aspects similar to other members of the ref, and that its production has an explanation that approximates (in some undefined degree) to a normal explanation for the production of members of the ref. Because a particular reproductive process need only approximate the 'perfect' reproductive process, it can produce imperfect copies, ones that malfunction.

Novelty

The historical theory's emphasis on the role of reproduction and selection has given rise to the thought that functional explanation, construed in this way, cannot explain novel behavior. On the historical account, it is inheritance from past (selected for) patterns of behavior that gives rise to the present functional behavior. However, to suppose that novel behavior cannot be produced by something whose function it is to produce that behavior is to underestimate the variety of functions. Millikan notes that there can be a relational proper function, which is a function to do something bearing a certain relation to something else. The chameleon's skin-color mechanism has the relational function of making the chameleon's skin match that of its environment (whatever that color may be). Given a specific color to adapt to, the mechanism then acquires an adapted proper function. So when it is sitting on a brown plant, the adapted proper function of the device is to produce brown skin. Crucial here is that the brown skin may have never been produced before, so it is not a member of a ref, and the production of it is not a direct proper function of the device. That to which an adapted device adapts is its adaptor (the brown plant being the adaptor in this case). One can extend this picture to include the functions of those who may

be consumers of the output of an adapted function. Consider the dance of the bees, which acts as a signal to other bees, 'telling' them to go southeast, where the nectar is to be found. This dance is adapted to the location of the nectar, so has an adapted function. The response it calls forth, the flight of the bees to the southeast, is adapted to this adapted function. It is not a short step to extend this approach to the communicative linguistic and other cultural capacities of human beings. Complications abound, but the fundamentals for doing this are in place. For the extension to be seen as a realistic prospect, two important features of these extensions of the historical approach need to be noted. The first is that functional explanation includes a normative aspect: a functional property is there in order to produce an effect, the effect being one it ought to cause, given that the property is instantiated here because past instantiations have produced that effect. Malfunctioning items are not doing what they ought to do. The extent to which functional explanation can account for psychological and sociocultural properties is partly dependent upon whether the normativity intrinsic to these latter properties can be explicated by the norms of functional explanation.

The second is that the above extensions indicate the explanatory reach of that theory. Any items (including patterns of behavior (e.g., rituals), social structures, ideas, 'memes'), can be the bearer of functions, provided that the basic conditions for this are met: variety, varied reproduction due to that variety. The reproduction need not be gene-centered, nor even broadly 'biological.' The transmission of bodies of knowledge and ways of behaving across generations is a form of reproduction, and so these items are possible bearers of functional properties. Whether they are or not depends on whether selection operates on these reproduced items, and here it is important to note that selection can take many forms. As behaviorists emphasized, behavior can be molded by painful experience, so pain is one selector. Emotional experience can be another. These have been called 'vicarious' or 'secondary' selectors (Campbell, 1960), indicating that they themselves have been selected for by natural selection, their purpose being to be local, less severe eradicators of those types of behavior that are inimical to the flourishing of the organisms that produce the behavior.

Given that reproduction and selection can be ubiquitous, it would appear that functional explanation has a much wider reach than once thought. Recent attempts to explain cultural evolution have utilized the flexibility afforded by the recognition of different 'selection regimes,' and so some cultural evolutionists talk of cultural and biological systems containing their own, interacting, evolutionary trajectories, thus resurrecting functional explanations in sociology but doing so with a selectionist foundation. Recent attempts to extend the Darwinian paradigm to culture include Boyd and Richerson (1985), Richerson and Boyd (2005), Cziko (1995), Dennett (1995), Runciman (2009), Heinrich and McElreath (2003), Hodgson and Knudsen (2010), Mesoudi (2011). For a discussion of functional explanation in the context of a Marxist theory of history, see Cohen (1979).

Proper and Actual Domains

One task of functional explanation is to assist in the explanation of why an animal, say, is exhibiting snake-avoiding behavior. If the behavior has been selected for because ancestors of those animals who behaved in that way in appropriate snake-populated environments lived longer, and so reproduced more prolifically, than those who did not, then one explains snake avoidance via its functionality. This suggests that the functional explanation is limited to only those behaviors targeted at types of inputs past tokens of which are responsible for the selection of the behavior – in this case, the presence of snakes. Some snakelike branches, however, might trigger the same behavior, and it is plausible to explain that behavior in the same way, as the triggering of a response that has been selected for. The snakes are said to form the proper domain of the function; the merely snakelike shapes are the actual domain (see Sperber and Hirschfeld, 2004 for a discussion of the proper domain–actual domain distinction).

There have, however, been suggestions that the explanatory scope of functional explanation has become too broad, that it is being abused by those who tend to see functionality everywhere, and that it is too narrow, not encompassing explanations of items that have no past history of selection, but are nevertheless beneficial to the organism. In the next section, these criticisms of the historical theory are reviewed.

Difficulties and Additions

Panglossianism

The etiological theory is supposed to explain the persistence and spread of a trait in terms of its adaptive history, such explanations involving historical claims as to why the feature being explained was adaptive, and then tying this adaptation to its present function. At times, it is extremely difficult to trace the relevant history, and the temptation is to ascribe functionality anyway, with the hope that the historical detail will be forthcoming. This has led to the accusation that such explanations are 'Panglossian,' presuming that this world is the 'biological best' world, one in which all features of organisms have some function or other (see Gould and Lewontin, 1978). This accusation is particularly relevant to the sociobiological explanations of psychological and social behaviors, as the relevant history supporting these explanations is often unknown. The complaint is a welcome caution against epistemologically unconstrained attributions of function, but does not attack the heart of the historical theory. It simply warns against its abuse.

Exaptations

A related worry about attributing functions incorrectly, also voiced by Gould (Gould and Vrba, 1982), concerns a trait that may be adaptive for one reason, but then change function in midstream, either doubling up in its functions or (because of environmental change may be) sloughing off the old function in favor of the new, without any change of structure. Now the present persistence of the trait cannot be explained via its previous adaptive history, as that would give a misleading account of its present function. Such a change in function has been called an exaptation. An example of such an exaptation is the wing feathers of birds, the function of which we now think is to enable birds to fly. A

selectionist story, however, would have to say that their function was as a thermal regulator, as that is what they were selected for originally. Clearly, some complication of the original selectionist theory is called for, but the complications are hardly unexpected. Causal explanation and accounts of causality in general have difficulties dealing with causal overdetermination, and what one has in the above examples is functional overdetermination. What one needs to say, in the functional case, is that the functions of an item are those fitness-enhancing effects that advantage (or advantaged) the bearer of the item relative to rivals, and that have been reproduced differentially in the relevant population. With the change of function of feathers from thermal regulation to flight, the stage at which some feathers produced a flight response would be critical in noting the acquisition of the new function. As soon as the feathered and flighted birds became preponderant, then one can say that the feathers had acquired a new function.

Dispositional and Virtual Selection

Once one notes that selection can be recent, a question arises as to how recent selection can be for functionality to be correctly attributed. To some extent, the answer will be vague; there seems no exact stage at which one can say, before now there was no function, but now there is. But given that selection can be recent, a natural suggestion will be that present selection suffices for functionality. The radical proposal is that history can be irrelevant, that the essential component in the historical theory is the contribution of a feature to the reproductive success of the item possessing that feature, and that a trait without any history of selection can be seen to be useful for its possessor in the precise sense of making a (future, or possible) positive contribution to the survival or reproductive capacity of the organism. This 'dispositional' or 'virtual' selectionism involves the recognition that selection does play some role in the attribution of functionality, but it need not be actual selection. Differential reproduction need not have taken place. On this account, a trait is functional because of its potential contribution to the fitness of the organism possessing the trait, given the environment in which the organism operates.

A weak version of this view can be developed by requiring the environment to engage actively with the trait, so that the trait can be seen to contribute positively to the organism's fitness. On this view, suitably developed, the trait is seen as being currently under a selection pressure. That is, it is seen as potentially contributing to the differential reproduction of those organisms with the trait, where 'potentially' only means 'barring accidents, it will contribute to the differential reproduction of those organisms.' So the weak view agrees with the historical view in all respects except that it allows for functionality prior to differential reproduction. The stronger interpretation does not require actual engagement with the selection-relevant environment; it only requires that there are factors present in the environment that could influence the organism's chances of reproduction and survival.

The crucial question facing these amendments to the historical theory is: what is the advantage in using the notion of function here? What does it add to a simple nonfunctional causal explanation of what is happening? On the historical view, part of the distinctive force of functional explanations derives from the normative elements implicated in attributions of function, the idea that the functional trait is there in order to do something. The selectionist story, cashed out in terms of differential reproduction, makes this normativity naturalistically respectable. Without the selection occurring, this distinctive feature of functional attribution is threatened.

It is clear that these accounts cannot give any functional explanation for the existence, proliferation, or shape of the trait. Take the first generation of long-necked giraffes. The existence of the long necks (their proliferation) cannot be given an explanation relating to the reproductively beneficial effect, which the long necks have had in the past. The only explanation seems to be a straightforward causal explanation in terms of mutations. A suggestion is that one change the explanandum, which is what Pettit (1996) does in his advocacy of virtual selection. The idea is that there can be an explanation of a fact that is not an explanation of its existence or actual persistence, but an explanation of why it would persist in certain nonactual conditions, an explanation of its resilience. This would be an explanation of the robustness of the fact under various hypothesized circumstances. An example given is that of equilibrium explanation, where the explanation of, say, a certain ratio of prey to predator in a given environment need not explain why this ratio (which is in fact an equilibrium) has come about – why it exists – but why, if disturbing influences were brought to bear upon it, it would return eventually to this ratio. It is in this sense that the resilience of the pattern is being explained. With functional explanation, the thought is that the absence of the operation of the function, the absence of the 'good' effect, may itself initiate certain mechanisms or processes that will reinstate the function's effect. So independently of how the trait performing the function emerged or proliferated, so long as it has this modal property of being reinstatable (in certain conditions) when disturbed, then the attribution of function will be in order. There will be something for that attribution to explain, namely, the resilience of the pattern.

The problem for the advocate of functions here is that a normal causal story, perhaps one with feedback built into it, seems adequate to the task of explaining what is going on. The notion of function adds nothing, or at least, the plausibility it has derives only from the systems idea of functions. There is a system here that works so as to maintain an item, or a pattern of behavior, and any subsystemic processes that work so as to maintain the item or behavior 'functions' to that end. There is nothing more that functional explanation does here, and, so far, this notion of functional explanation does not have the distinctive normative character that the historical account imparts to functionality.

One could, however, construe the notion of feedback as playing something like the role of selection, legitimizing the thought that when the continued presence of a feature (or of an organism possessing the feature) is dependent on the (past) effects that it has caused, then that feature has acquired the function to produce those effects. This would still be an historical account of functionality, depending as it does on past effects, but it extends the application of functionality from features of variably reproduced items to features of variably persisting items (see McLaughlin, 2001: chapter 8).

The Explanandum

There is some debate about what it is that a functional explanation explains. One suggestion is that, given selection only 'chooses' among the traits that are in existence, favoring some at the expense of others, all it can explain is why there are (so many) items with that feature. The proposal is that selection cannot explain how individuals come to have the traits that they do have. The explanation for the traits possessed by any individual would be simply the causal story instantiated in the genetic processes that produced the trait in that individual. Sober (1984) called this latter type of explanation developmental explanation, and the good point he was making was that selection operates on traits already in existence.

One can accept this point, however, and still deny that all that functional explanation can explain is the very general fact concerning the proliferation rates of the causally explained traits. Neander has pointed out that each such trait will have an evolutionary history, the elaboration of which will show how the trait came to have the form it now has (Neander, 1995). Given the falsity of saltationist doctrines, traits such as opposable thumbs or long necks did not emerge fully fledged; there were many mutations, and those that increased, say, opposable thumbness were favored. A restriction to looking at 'selection of preexisting traits' has almost an air of saltationism about it. It is as though the traits came into existence formed as they now are, and were then selected for on that basis. Ignoring the more gradual, at times almost imperceptible, changes that took place in order to arrive at the present trait is to ignore a part of the explanation as to why the trait is what it is. It is because functions can be performed by different mechanisms that attending to the historical detail is important in showing how and why this mechanism evolved into its present form. The central point is that, although selection does only distribute characteristics, the history of successive distributions shows selection as also molding those characteristics. And, as Forber points out (Forber, 2005), sometimes a novel trait only emerges in an environment where selection has produced relevant precursors to that trait, such precursors being essential to the viability of the new trait. Thus, an explanation of the evolution of the human eye, for example, needs to pay attention to how selection operated on protoeyes, forming the necessary background for the emergence of adaptive fully formed eyes.

Abstract

The study of human brain function using functional magnetic resonance imaging (fMRI) has exploded in the past decade. A standard fMRI study results in enormous amounts of data. In addition, the signal of interest is relatively weak and the data exhibit a complicated temporal and spatial noise structure. In this article, we provide an overview of the analysis of fMRI data, from the initial data acquisition to its use in locating brain activity, making inference about brain connectivity and predictions about psychological or disease states.

Introduction

Functional magnetic resonance imaging (fMRI) is a noninvasive technique for studying brain activity. During the course of an fMRI experiment, a series of brain images are acquired while the subject engages in a set of tasks. Changes in the measured signal between images are used to make inferences regarding possible task-related activations in the brain. There are several common objectives in the analysis of fMRI data, including localizing regions of the brain activated by a task, determining distributed networks that correspond to brain function, and making predictions about psychological or disease states.

Together with other neuroimaging modalities, such as positron emission tomography, electroencephalography (EEG), and magnetoencephalography, fMRI has provided researchers with unprecedented access to the brain in action and numerous insights into human brain function. In recent years, fMRI, in particular, has experienced an explosive growth and found applications in a wide variety of fields, such as psychology, economics, political science, computer science, and statistics. In addition, the use of fMRI data is central to the emerging fields of cognitive neuroscience, affective neuroscience, neuroeconomics, and other related neurobehavioral disciplines. In these areas, fMRI data are being combined with data on performance and psychophysiology to yield new models of human thought, emotion, and behavior, as well as to confirm existing theories.

Any given fMRI experiment gives rise to massive amounts of data. In addition, the signal of interest is relatively weak and the data exhibit a complicated temporal and spatial noise structure. The area of research surrounding fMRI has given rise to a number of interesting and important statistical problems that cover a variety of topics, including the acquisition of raw data, image reconstruction, experimental design, preprocessing, and data analysis (Lindquist, 2008).

Data Structure

During the course of an fMRI experiment, a series of three-dimensional brain images are acquired while the subject performs a set of tasks. Each image consists of roughly 100 000 uniformly spaced volume elements, or voxels, that partition the brain into equally sized boxes. Each voxel corresponds to a spatial location and has a number associated with it that represents its intensity, which is related to the spatial distribution of the nuclear spin density in that area. During the course of an fMRI experiment, between 100 and 2000 images of this type are acquired. The time between each acquisition is referred to as the TR of the experiment, and is typically around 2 s. Intensity values from each individual voxel can be extracted to create a time series of length T, where T corresponds to the number of acquired images. See Figure 1 for an illustration.

A standard fMRI study is performed on multiple subjects (e.g., 10–50) brought in for multiple scanning sessions, each consisting of a number of runs (replications of a certain task). On top of that, multiple high-resolution structural scans are collected for preprocessing and presentation purposes, and often diffusion tensor imaging (DTI) is also collected to inform subsequent network analyses. In sum, the total amount of data that needs to be analyzed is enormous.

Data Acquisition and Reconstruction

To collect fMRI data, the subject is placed into a magnetic resonance imaging scanner, which consists of an electromagnet with a very strong magnetic field (typically between 1.5 and 7.0 Tesla for human studies). This scanner is extremely versatile and can be used to study brain structure, brain function, and even the manner in which water diffusion takes place in the brain.

During data acquisition, the subject is exposed to a radio-frequency (RF) electromagnetic field pulse. This causes the nuclei of interest (e.g., hydrogen atoms) to absorb the energy at a particular frequency band, and become 'excited.' After the pulse is removed, the nuclei emit the energy at the same frequency as they 'relax,' and this quantity can be measured. Pulse sequences that implement particular RF pulses and manipulations of the magnetic field's shape are used to acquire data that can be reconstructed into a map of the underlying signal sources (the hydrogen atoms), thus providing an image of the brain. For a more in-depth discussion see Huettel et al. (2004) or Haacke et al. (1999).

The relaxation process can be described by three different values: T1, T2, and T2*. T1 and T2 are time constants that depend upon tissue type. T1 refers to the rate at which spins relax back to alignment with the main magnetic field, and T2

Figure 1 An image consists of roughly 100 000 brain voxels, each corresponding to a spatial location and an intensity value. During the course of an experiment T images are acquired. Extracting the data from a single voxel allows us to track its intensity over time and relates it to some experimental paradigm.

to the rate of attenuation of the magnetic field applied by the RF pulse. T2* is similar to T2; in addition, it depends on local inhomogeneities in the magnetic field caused by changes in blood flow and oxygenation. Different pulse sequences are used to produce images sensitive primarily to T1, T2, or T2*. Because T1 and T2 vary with tissue type, T1- and T2-weighted images can be used to provide detailed representations of the boundaries between gray matter, white matter, and cerebrospinal fluid. Because T2* is sensitive to flow and oxygenation, T2*-weighting is used to create images that can be used to study brain function.

The most popular approach toward fMRI, the blood oxygenation level-dependent (BOLD) contrast (Kwong et al., 1992; Ogawa et al., 1992), takes advantage of the difference in T2* between oxygenated and deoxygenated hemoglobin. As neural activity increases, so do metabolic demands for oxygen and nutrients. Neural firing leads to the extraction of oxygen from hemoglobin in the blood. As oxygen is extracted, the hemoglobin becomes paramagnetic, creating small distortions in the magnetic field that cause a T2* decrease (i.e., a faster decay of the signal). Thus, increases in deoxyhemoglobin lead to a decrease in BOLD signal that can be measured by the scanner.

Properties of the BOLD Response

The temporal resolution of fMRI is generally not limited by how quickly the data can be acquired, but instead by properties of the underlying evoked hemodynamic response to a certain neural event. The BOLD response is a complex, nonlinear function that depends on neuronal and vascular changes (Wager et al., 2005). The shape of the response depends both on the applied stimulus and the hemodynamic response to neuronal events; the latter is typically referred to as the hemodynamic response function (HRF), shown in Figure 2(a). The increased metabolic demands due to neuronal activity lead to increases in the inflow of oxygenated blood to active regions of the brain. Since more oxygen is supplied than consumed,

Figure 2 (a) The standard canonical hemodynamic response function (HRF) used in functional magnetic resonance imaging (fMRI) data analysis. (b) The blood oxygenation level dependent (BOLD) response is often modeled as the convolution of the stimulus function and the HRF. Here are sample responses for a blocked design (top) and an event-related design (bottom).

this leads to a decrease in the concentration of deoxyhemoglobin and an increase in signal. This rise in signal peaks 5–8 s after the onset of neural activity. Thereafter, the BOLD signal decreases to below a baseline level, which is sustained for roughly 10 s. This effect, the poststimulus undershoot, is due to the fact that blood flow decreases more rapidly than blood volume, allowing for a greater concentration of deoxyhemoglobin in previously active brain regions.

It is common to assume a linear relationship between neuronal activity and the BOLD response, where linearity implies that the magnitude and shape of the evoked HRF do not depend on the preceding stimuli. Studies have shown this to be a reasonable assumption (Boynton et al., 1996), as long as events are spaced at least 5 s apart (Miezin et al., 2000). The ability to assume linearity is important, as it allows the relationship between stimuli and BOLD response to be modeled using a linear time invariant system, where the stimulus acts as the input and the HRF acts as the impulse response function. This relationship is shown in **Figure 2(b)**.

The timing and shape of the HRF are known to vary across a single subject's brain and across individuals (Aguirre et al., 1998). Part of this variability is vascular, which may cause differences in the HRF across brain regions in the same task for purely physiological reasons (Vazquez et al., 2006). Another source of variability is differences in the pattern of evoked neural activity in regions performing different functions related to the same task. It is important that these regional variations are accounted for when modeling the BOLD signal.

The BOLD response is corrupted by random noise and various nuisance components that arise due to both hardware reasons and the subjects. For instance, fluctuations in the magnetic resonance signal intensity caused by thermal motion of electrons within the subject and the scanner give rise to noise that tends to be highly random and independent of the experimental task. This type of noise does not exhibit spatial structure and its effects can be minimized by averaging data. Another source of variability is due to scanner drift, caused by scanner instabilities, which result in slow changes in voxel intensity over time. The amount of drift varies across space, and it is important to include this source of variation in subsequent models. Finally, physiological noise due to patient motion, respiration, and heartbeat all cause fluctuations in signal across both space and time, which should be accounted for if possible.

Experimental Designs

Designing an fMRI study involves a trade-off between experimental power and the ability to make strong inferences based on the results. The two main types of experimental designs used in fMRI are blocked designs and event-related designs. In a blocked design, different conditions in the experiment are presented as separate blocks of trials, each for an extended period of time. In event-related designs, discrete events of short duration are presented in a randomized order. Examples of these two design types are shown in **Figure 2(b)**.

Blocked designs typically yield high experimental power, but do not provide precise information about the particular psychological processes that activated a brain region. Event-related designs, on the other hand, allow brain activation to be linked more precisely to the particular cognitive processes engaged in certain types of trials, but suffer from decreased power. These types of designs rely more strongly on assumptions about the time course of both evoked neural activity and the HRF, and it is common to assume a near-instantaneous neural response for brief events and a canonical HRF shape to generate linear models for statistical analyses. Blocked designs tend to be less sensitive to the variability of the HRF because they depend on the total activation caused by a train of stimulus events, which makes the overall predicted response less sensitive to variations in the shape of responses to a single event.

Preprocessing

Prior to analysis, fMRI data undergo a series of preprocessing steps. The goals of preprocessing include minimizing the influence of data acquisition and physiological artifacts, checking statistical assumptions and transforming the data to meet assumptions, and standardizing the locations of brain regions across subjects to achieve validity and sensitivity in group analysis. Below we outline the most common preprocessing steps.

Statistical analysis typically assumes that every voxel in an image is acquired simultaneously. In reality, fMRI data are collected in a slice-wise manner, so data from different slices are shifted in time relative to one another. Therefore, it is common to estimate the signal intensity in all voxels at the same moment in the acquisition period, in a process referred to as slice-timing correction. This can be done by interpolating the signal at the chosen time point using information from the same voxel measured in adjacent acquisitions. Some researchers do not use slice timing, as it adds potential interpolation error to the data, but instead use more flexible hemodynamic models to account for variations in acquisition time.

Subject motion during data acquisition causes a voxel's signal intensity to be 'contaminated' by signal from its neighbors. Therefore, it is critical to realign each individual image to compensate for subject movement. This is typically performed by choosing a reference image (e.g., the first image) and using a rigid body transformation, which allows images to be translated and rotated, to match each image to the reference. An iterative algorithm is used to search for the transformation parameters that provide the best match. While realignment is able to correct small movements of the head, it does not correct for the more complex 'spin-history artifacts' created by motion (Friston et al., 1996). Therefore, parameter estimates at each time point are often included in the later statistical analysis as covariates of no interest.

Coregistration is the process of aligning structural and functional images. This procedure is performed both for presentation purposes and to aid in later preprocessing steps. Here a single structural image is mapped onto the first, or mean, functional image. This is typically performed using an affine transformation matrix whose parameters can be estimated by maximizing the mutual information between the two images.

For group analysis, it is necessary for each voxel to lie within the same brain structure for each subject. However, it is well known that individual brains have different shapes and features. Normalization attempts to register each subject's anatomy with a standardized atlas space defined by a template brain, such as the Talairach or Montreal Neurological Institute brain (Evans et al., 1993; Talairach and Tournoux, 1988). Normalization can be linear, involving simple registration of the gross shape of the brain, or nonlinear, involving warping to match local features, and is typically performed by matching a subject's structural scan to the template brain. If coregistration has been performed, the same transformation can thereafter be applied to each functional image.

Finally, many investigators apply spatial smoothing to the functional data, thereby blurring their intensities in space. One reason is to improve intersubject registration and remove possible artifacts related to that procedure. A second reason is to validate certain modeling assumption regarding image smoothness and normality. Finally, if activation is occurring over several voxels, smoothing can help increase the signal-to-noise ratio. Smoothing is typically performed by convolving each image with a Gaussian kernel described by the full width of the kernel at half its maximum height, measured in millimeters.

Data Analysis

The statistical analysis of fMRI data has a variety of goals. These include localizing brain areas activated by a task, determining networks corresponding to brain function, and making predictions about psychological or disease states; see Figure 3 for illustrations. We briefly outline each of these goals below; for more information see Lindquist (2008).

Localizing Brain Activation

To date, the most common use of fMRI data has been to detect areas of the brain that activate in response to a specific task. Brain mapping studies are necessary for the development of biological markers and increasing our understanding of brain function. Typically, data analysis is performed using the so-called massive univariate approach, where a separate model is constructed and fit to data from each voxel.

The general linear model (GLM) approach of Worsley and Friston (1995) has arguably become the dominant way to analyze fMRI data. It models the fMRI time series in each voxel as a linear combination of several different signal components and tests whether it is systematically related to any of these known input functions. Using the GLM, the data at each voxel can be expressed as $\mathbf{Y} = \mathbf{X}\beta + \varepsilon$, where $\varepsilon \sim N(0,\mathbf{V})$. Here $\mathbf{Y}$ represents the data (a vector of length T), $\mathbf{X}$ is a design matrix containing information about various signal components, and $\mathbf{V}$ is a covariance matrix that incorporates information about autocorrelations in the data, typically modeled using either an autoregressive or an autoregressive moving-average model.

Proper construction of the design matrix is critical when using the GLM. This is complicated by a number of factors, including the fact that the BOLD response contains low-frequency drift and artifacts related to head movement and

Figure 3 (a) An example of a thresholded statistical map shows activation in the visual and motor cortices (Lindquist, M., Zhang, C., Glover, G., Shepp, L., 2008b. Rapid three-dimensional functional magnetic resonance imaging of the negative BOLD response. Journal of Magnetic Resonance 191 (1), 100–111). (b) An undirected graph, obtained using an inverse covariance matrix estimation technique, shows the relationship between several brain regions and heart rate during a stress task (Cribben, I., Haraldsdottir, R., Atlas, L.Y., Wager, T.D., Lindquist, M.A., 2012. Dynamic connectivity regression: determining state-related changes in brain connectivity. NeuroImage 61 (4), 907–920). (c) An illustration of a pain biomarker (Wager, T.D., Atlas, L.Y., Lindquist, M.A., Roy, M., Woo, C.-W., Kross, E., 2013. An fMRI-based neurologic signature of physical pain. New England Journal of Medicine 368 (15), 1388–1397), where the cross product of the data **x** and voxel weights **w** provides scores that allows us to classify subjects.

cardiopulmonary-induced brain movement, the neural response shape may not be known, and the hemodynamic response varies in shape across the brain. For these reasons, the design matrix **X** usually consists of both nuisance parameters (corresponding to drift components and the estimated motion parameters) and signal of interest. The simplest version of the GLM assumes that both the stimulus function and the HRF are known. The stimulus is assumed to be equivalent to the experimental paradigm, while the HRF is modeled using a canonical HRF, typically either a gamma function or the difference between two gamma functions (see **Figure 2(a)**). Under these assumptions, the convolution of the stimulus and HRF is used to summarize the BOLD response and entered as a column of **X**; see **Figure 2(b)** for examples corresponding to a blocked design and an event-related design. If one is unwilling to assume a fixed canonical HRF, it is possible to model the shape by expressing the HRF as the linear combination of basis functions. Here each basis function is convolved with the stimulus and entered as separate columns in the design matrix (Lindquist and Wager, 2007; Lindquist et al., 2008a).

After fitting the model, one can test for an effect $\mathbf{c}^T\beta$ where **c** is a contrast vector. The contrast vector can, for example, be used to estimate signal amplitudes in response to a single condition, an average over multiple conditions or the difference in amplitude between two conditions. Significance is determined by testing individual model parameters using a t-test, and subsets of parameters using an F-test. Since the covariance matrix has to be estimated, a Satterthwaite approximation is used to calculate the effective degrees of freedom for the test statistics. This procedure is repeated across all brain voxels and the results are summarized in a statistical map, which is an image of each voxel's test statistic.

The next step is to threshold these maps, with the implication that significant voxels are activated by the experimental task (see **Figure 3(a)**). In a typical experiment, up to 100 000 hypothesis tests (one for each voxel) are performed simultaneously, and it is crucial to correct for multiple comparisons when determining the threshold. Several approaches toward controlling the false-positive rate have been used, with the fundamental difference between methods lying in whether they control the family-wise error rate (FWER) or the false discovery rate (FDR).

Random field theory (Worsley et al., 2004) is the most popular approach for controlling the FWER in the fMRI community. Here, the image of voxel-wise test statistic values are assumed to be a discrete sampling of a continuous smooth random field. One begins by estimating the smoothness of the image, expressed in terms of resolution elements, or resels. Next, using information about the number of resels and the shape of the search volume, mathematical theory exists for calculating the expected Euler characteristic. For large thresholds, this value is equal to the number of clusters of activity that one would expect by chance at a certain statistical threshold. Hence, it can be used to determine the appropriate threshold that controls the FWER at a certain level.

The FDR controls the proportion of false positives among all rejected tests (Genovese et al., 2002). The FDR controlling procedure is adaptive in the sense that the larger the signal, the lower the threshold. If all of the null hypotheses are true, the FDR will be equivalent to the FWER. In addition, any procedure that controls the FWER will also control the FDR. Hence, any procedure that controls the FDR can only be less stringent and lead to increased power.

So far, the discussion has centered on single-subject analysis. However, researchers typically want to make conclusions on population effects, and statistical analysis needs to be extended to incorporate information from groups of subjects. Multisubject fMRI data are intrinsically hierarchical in nature, with lower level observations (i.e., individual subjects) nested within higher levels (i.e., groups of subjects). Standard mixed effects models can be used to analyze multisubject fMRI data. However, it is most common to fit separate GLMs for each subject and perform a t-test on a particular contrast of interest at the second level (Mumford and Nichols, 2009).

Connectivity

Recently, there has been enormous interest in performing connectivity studies that describe how various brain regions interact and how these interactions depend on experimental conditions. It is common in the fMRI literature to distinguish between functional and effective connectivity (Friston, 1994). Functional connectivity is defined as the undirected association between two or more fMRI time series, while effective connectivity is the directed influence of one brain region on others.

The simplest approach toward functional connectivity analyses compares correlations between regions of interest, or between a 'seed region' and other voxels throughout the brain. Recently, inverse covariance estimation methods have been applied since, for multivariate normal data, conditional independence between variables (regions) corresponds to zero entries in the inverse covariance matrix (see **Figure 3(b)**). Other approaches include using multivariate decomposition methods, such as principal components analysis (Andersen et al., 1999) and independent components analysis (Calhoun et al., 2001; McKeown and Makeig, 1998), to identify task-related patterns of brain activation without making a priori assumptions about its form. These methods involve decomposing the time-by-voxel data matrix, **Y**, into a set of spatial and temporal components according to some criteria (e.g., independence between components). These types of approaches have been especially fruitful for analyzing so-called resting-state data (Biswal et al., 1995), where the subject lies in a scanner without performing a specific task. This is an area of intense research where standard methods for localizing brain activation are not applicable due to the lack of stimulus.

In effective connectivity, a small set of regions with a proposed set of directed connections are specified a priori, and tests are used to assess the statistical significance of individual connections. Most effective connectivity methods rely on two models: a neuroanatomical model that describes the areas of interest, and a mathematical model that describes how they are connected. Commonly used methods include structural equation modeling (McIntosh and Gonzalez-Lima, 1994) and dynamic causal modeling (Friston et al., 2003). Granger causality (Roebroeck et al., 2005) is another approach used to test effective connectivity. This approach does not necessarily rely on a structural model, but instead quantifies the usefulness of past values extracted from one brain region in predicting current values in another.

Prediction

There is a growing interest in using fMRI data for classification of mental disorder and predicting the early onset of disease. In addition, there is interest in developing methods for predicting stimuli directly from functional data. This opens up the possibility of inferring information about subjective human experience directly from brain activation patterns. (See Pereira et al. (2009) for an overview.)

Predicting brain states is challenging and requires the application of novel statistical and machine learning techniques. Various techniques have successfully been applied to fMRI data in which a classifier is trained to discriminate between different brain states and then used to predict the states in a new set of fMRI data. The application of machine learning methods to fMRI data is often referred to as multivoxel pattern analysis (MVPA). Instead of focusing on single voxels, MVPA uses pattern-classification algorithms applied to multiple voxels to decode patterns of activity. In MVPA the goal is to determine the model parameters that allow for the most accurate prediction of new observations (see **Figure 3(c)**).

In fMRI it is particularly important to make analysis choices that balance interpretability with predictive power. Certain methods may give good predictions but the resulting voxel weights may be difficult to interpret and may not generalize well to new subjects.

What the Future Holds

In neuroscience there is a general trend toward using multiple imaging methods in tandem to overcome limitations of each approach in isolation. For example, advances in engineering and signal processing allow EEG and fMRI data to be collected simultaneously (Goldman et al., 2000). EEG has an extremely high temporal resolution (on the order of milliseconds) but poor spatial resolution, while fMRI suffers from the opposite problem. By merging these two techniques, the hope is that one can get the best of both worlds. In another example, DTI, a technique for measuring directional diffusion and reconstructing the fiber tracts of the brain (Le Bihan et al., 2001), can be combined with fMRI to determine appropriate regions of the brain to include in subsequent connectivity models. In yet another example, neuroimaging data are being combined with transcranial magnetic stimulation (TMS) to integrate the ability of neuroimaging to observe brain activity with the ability of TMS to manipulate brain function (Bohning et al., 1997). Using this technique, one can stimulate or suppress activation in certain regions while the subject performs certain tasks. One can then attempt to infer causal relationships by studying differences in a brain network when a region is manipulated and when it is not. Finally, integrating genetics with brain imaging is seen as a way to study how a particular subset of polymorphisms may affect functional brain activity. In addition, quantitative indicators of brain function could facilitate the identification of the genetic determinants of complex brain-related disorders such as autism, dementia, and schizophrenia (Glahn et al., 2007).

Each of these multimodal approaches promise to be important topics of future research, and to fully realize their promise, novel statistical techniques will be needed. Ultimately, combining information from different modalities will be challenging to data analysts, if for no other reason than that the amount of data will significantly increase. In addition, since different modalities are measuring fundamentally different quantities, it is not immediately clear how to best combine the information. However, clearly, this is an extremely important problem that has already started to become a major area of research.

Functionalism in Anthropology

Abstract

Functionalism is a sociological research program of historical and systematic significance. Sociological explanations in terms of functions are teleological. Social phenomena are to be explained by their effects and consequences – chiefly of a beneficial, morally desired or nonintended character – and/or by a circuit of equilibration (a homeostatic loop) which is maintaining a certain state of proper functioning. The notion of (mono-) functionally specialized subsystems of society can be seen as the most important precipitate of functionalist thinking in sociology.

In its simplest common-sense form functionalism in anthropology describes approaches which purport to explain cultural or social phenomena in terms of the purpose they serve.

Since the 1960s, specialized research into the sociological and historical framing of anthropology has revealed the extent to which discussions of functionalism contribute to analysis of knowledge as culture. As yet, however, it falls short of meeting the criticism that it tends to treat the discipline of anthropology as a closed discourse, despite calls that it be viewed as part of a larger discursive field in which anthropology operates (Asad, in Stocking, 1991; Trouillot, in Fox, 1991).

The Intellectual History of an Idea

The term 'function' was first introduced as a mathematical concept by Gottfried Wilhelm Leibniz in 1714, to refer to a variable considered in relation to one or more other variables in terms of which it might be expressed.

Two main bundles of ideas underlay the concept of 'function' that dominated academic anthropology in the first half of the twentieth century: (a) a relation of interdependence and (b) an orientation toward given ends. The first involved reciprocity and reversibility in terms of cause and effect. The ends might be the needs of the individual, as in the utilitarian functionalism of Malinowski (1884–1942) or the needs of society, as in the structural–functionalism of Radcliffe-Brown (1881–1955). Both adopted notions of culture or society in the modern pluralized usage as totalities with a certain unity and integrative character, a notion derived from the German philosopher Johann Gottfried Herder.

In the second half of the century, the premise remained that cultures and societies were structured wholes, now more consistently referred to as cultural or social systems. At this point functionalism's orthodoxy came under challenge in the aftermath to the Second World War which saw the withdrawal of sovereignty claims over a plethora of colonial territories within the British Empire and the establishment of United States 'trusteeship' in Oceania. This spurred British functionalists to address complex 'new nations' and provided American anthropologists *de novo* with a laboratory of functioning colonial cultures (Bashkow, in Stocking, 1991).

By the 1970s, functionalism (as an achieved, shared paradigm which defined problems and procedures) was seen to be outmoded. It was replaced, amidst repeated calls for anthropology to reinvent itself, by struggle among new modes of discourse, chief among them Levi–Straussian structuralism, Marxism, and symbolic and interpretive anthropology. Nevertheless, echoes of functionalism lingered on into the decentered, fragmented, pluralizing, flexible, refractive, postmodern world of the new millennium.

Functionalism's Multivocality

A distinction among (a) functionalism as doctrine (or theory); (b) functionalism as method; and (c) functionalism as interest or ideology was a critical feature in Bronislaw Malinowski's modernist legacy to functionalism (Vincent, 1991). This, along with the essential dualism between natural science and the humanities (particularly science and history) that entered modernist anthropology with Franz Boas's *The Study of Geography* (1897, reprinted in Stocking, 1996), goes some way towards ordering the cultural complexity of functionalist knowledge. The scientific tendencies of the physicist who tries theoretically to reduce reality to simple elements and the humanist tendencies of the cosmographer who seeks to comprehend a complex phenomenon as a whole are both contained within the functionalist moment in anthropology.

Functionalism as Doctrine or Theory

Three cross-cutting anthropological trajectories may be recognized within functionalist anthropology.

Utilitarian Functionalism (Malinowskian)

Recent research has exposed the extent to which Malinowski's utilitarian functionalism, which dominated British anthropology between the wars, derived from his engagement with the neopositivism of Ernst Mach in his doctoral dissertation – particularly Mach's view that knowledge is a response to biological human needs (Thornton, 1985; Thornton and Skalnik, 1993). In his last, posthumously published, position paper, *The Functional Theory*, Malinowski takes his stand on two axioms: first, that every culture must satisfy the

biological system of needs, and second, that every cultural achievement that implies the use of artifacts or symbols is an instrumental enhancement of human anatomy, and refers directly or indirectly to the satisfaction of a bodily need (Malinowski, 1944, p. 171).

Strictly followed, these axioms would restrict cultural anthropology to the economism of the rationalizing individual (human nature), or the ecologism of selective advantage (external nature) (Sahlins, 1976), but Malinowski's practice deviated considerably from his theorizing. As with Boas, his sentient functionalism lay immanent in his ethnography; neither man was deemed 'a theorist.'

Hybrid Cultural Functionalisms (Boasian/Parsonian)

This complex functionalist trajectory, triggered by Franz Boas's (1858–1942) 'vaguely functionalist ideas' (Sahlins, 1976, p. 71), drew explicitly on German humanist intellectual traditions. It comprised several contradictions which manifested themselves transgenerationally. Initially this took the form of Alfred Kroeber's (1876–1960) functionalist historicism and Robert Lowie's (1883–1957) neopositivist empiricism. A second generation was further divided; it was also developing in the context of the 'British' functionalist paradigm.

Thus, in 1934, Alexander Lesser (1902–82), recognizing functionalism as the most vigorous tendency extant in anthropology, set out to distinguish the particular interests and conceptions of individual American functionalists from the broader, foundational Boasian functionalist approach. He adopted a Leibnizian mathematical definition of a functional relation, established by observation, while arguing that contemporaneous events associated by the observer might be merely coexistences. Functional historicity recognized that 'institutions, customs, beliefs, artifacts have careers in time, and that their form and character is molded more by what has happened to them in the course of that history than by what particular things they occur associated with at any one time' (Lesser in Mintz, 1985, p. 60). Radcliffe-Brown's position paper 'On the concept of function in social science' (1935) was prompted by his taking Lesser's critique personally.

It was actually directed at Lesser's fellow Boasians at Columbia University in New York, Ruth Benedict (1887–1948) and Margaret Mead (1901–78). Romantic holistic sensibility figured most prominently in Benedict's cultural configurations or patterns of culture. Mead, on the other hand (after corresponding with Radcliffe-Brown), designed a framework for the comparative functional analysis of social systems. This was published in *Cooperation and Competition among Primitive Peoples* (1937).

At the same time a more scientific anthroposociological functionalism was being developed at Harvard where sociologist Talcott Parsons (1902–79) joined forces with anthropology to set up a Department of Social Relations. One of its earliest products was arguably the most thoroughgoing functionalist ethnography ever published, Conrad Arensberg and Solon Kimball's *Family and Community in Ireland* (1940). Under the direction of W. Lloyd Warner (formerly Radcliffe-Brown's student) this extended functionalist anthropology from simple/primitive to complex/modern cultures. Later critics faulted the work for presenting as eternally cultural what was no more than a well-observed historical moment in county Clare.

Structural-Functionalism (Radcliffe-Brown)

Structural-functionalism's core concepts are, in harness, structure and system. Under the auspices of Radcliffe-Brown (1881–1955) it emerged as a clear-cut alternative to hybrid Boasian functionalism and successor to Malinowski's particular brand of economism and radical individualism. It derived not from German and British precursors but mainly from Durkheimian French sociology with supplementary insights from the Russian geographer and anarchist, Peter Kropotkin (1842–1921).

Structural-functionalism emphasized the formal ordering of parts and their functional interrelations as contributing to the maintenance needs of a structured social system. The function of any institution (or 'recurrent social activity') was the part it played in the maintenance of the larger structural whole. This assumption attributed to social systems an internal integration of parts similar to that found in organisms.

Whereas Malinowskian functionalism was seen to have outworn its usefulness by 1945, and American cultural functionalism remained factionally divided, Radcliffe-Brown's successors, particularly Meyer Fortes (1906–83), Edward Evans-Pritchard (1902–73), and Max Gluckman (1911–75), expanded structural-functionalism to address situation, selection, and history while continuing to work implicitly with equilibrium models of processes internal to the sociocultural system. Marxisant anthropological analyses of contradictions in structure and function supplemented structural-functionalism with a compatible, historically oriented, approach to competition, conflict, and change.

Functionalism as Method

Malinowski claimed that the so-called functional method in modern anthropology constituted a specific and necessary method of knowledge production. The relationship between theory and practice was reciprocal. Practice consisted of the intensive fieldwork that had emerged in contradistinction to the scientific survey methods of the Cambridge University Torres Straits Expedition of 1898–9, and the writing up of research findings in monographic form. The 1912 edition of *Notes and Queries*, that Malinowski carried with him into the field, contained W. H. R. Rivers, (1864–1922) delineation of 'intensive' fieldwork in which 'the worker lives for a year or more among a community of perhaps four or five hundred people and studies every detail of their life and culture; in which he comes to know every member of the community personally; in which he is not content with generalized information, but studies every feature of life and custom in concrete detail and by means of the vernacular language' (Rivers 1913, p. 7, quoted in Urry, 1993, p. 28). This became functionalism's ideal mode of production.

Functionalism's methods of reproduction (knowledge as culture) included grantsmanship, correspondence, seminars, public events, unpublished and published lectures, oral histories, biographies, and the writing of monographs. Commemorations and conferences held in Cracow, London, and New York to memorialize Malinowski in 1984

(Gellner, 1987) and in America to memorialize Boas in 1992 exposed a more complex functionalist heritage than that commonly recognized.

Paradigmatic adjustment was essential to the production and reproduction of functionalism. Thus, the last volume of Malinowski's Trobriand ethnography, *Coral Gardens and their Magic* (1935), documents the extent to which he was beginning to question 'the wholeness of culture,' criticize his neglect of the colonial order and of the inadequacy of the concept of culture contact or acculturation. He noted the possibility of placing his own functional analyses of land tenure in the same frame as political controversy over land rights in Ireland and India (Vincent, 1991). But such paradigmatic adjustment was rare. More routinely, it was the thick, detailed ethnographies functionalism engendered that empowered the reader to re-evaluate functionalism long before the textualization of theory became emblematic of paradigmatic change. The perdurance of a romantic ethnographic tradition contributed significantly to the persistence of inherent functionalist notions in anthropology even when the theoretical adequacy of functionalism remained an issue (Gellner, 1987).

Functionalism as Interest: The 'Functionalist Movement'

Functionalism was both a concept and a scientific community contesting the constitution and distribution of cultural capital. Throughout the first three decades of the twentieth century in both Britain and America evolutionism, diffusionism and functionalism represented warring trajectories and interests and the paradigmatic dominance of functionalism was by no means secure (Vincent, 1986). Explanations of dominance, as George Stocking has consistently demonstrated, are to be found not in the valency of ideas but in academic power, control, and institutionalization – to which observation must be added strategies of reproduction. In anthropology departments where field materials were presented in seminars (as at the London School of Economics and Manchester) 'fieldnotes were treated as facts, as concrete things, as sources of authority, as weapons in the struggle to gain the high ground of functionalist debate' (Bond in Sanjek, 1990, p. 279).

Methodological Issues or Problems in Functionalism

As with other -isms, functionalism has been described most clearly and simply by those with most to gain from detracting interest from it. Yet anthropological functionalism has been characterized by constant immanent critique as well as external challenge. For critics it has been something of a moveable feast. What is noted depends on whose functionalism they are addressing and at what phase in that functionalist's thinking. Broad, generic charges laid against anthropological functionalism relate to positivism and pragmatism, on the one hand, and primitivism, on the other. Specific critiques have been directed against its holism along with its assumption of interdependence of parts, synchronism, homogeneity and the notion of collective consciousness, uniformity and its transgenerational replication through custom. Re-evaluations of structural-functional classics demonstrated that even so-called simple societies/cultures were internally differentiated and heterogeneity gave rise to conflicting concerns among different sectors of the population. As the paradigm expanded further, new charges were made that functionalism could not accommodate the analysis of power.

Conclusion

The radical antipositivism of the 1960s put functionalism on trial. Functional anthropologists who declined to commit anthropology to the scrap heap argued ethnography's value as social history. Others argued its continued relevance for specific subfields such as ecological and applied anthropology.

It is not likely that future theoretical and research problems will follow the trends set by functionalism except, perhaps, in re-evaluations of problems in Foucault's adoption of functional terminology in his conceptualization of 'discourse'; in the work of anthropologists who holistically find instances of cultural resistance to what they perceive to be Gramscian style 'hegemony'; and in the relationship of anthropological functionalism to other modernisms (Webster, in Manganaro, 1990).

The main thrust is likely to be the further undercutting of the two pluralized concepts integral to functionalism: 'cultures' and 'societies' (Wolf, 1988; Barth, 1992). This new emergent paradigm, 'New Critical Theory,' retains functionalism on its agenda, albeit in a literary and historical mode. It promises to further problematics addressed by anthropological historical realism (sometimes in the guise of political economy) and postinterpretive cultural critique. In both instances, functionalism, in anthropology, lingers on (just as evolutionism and diffusionism linger on) not just as situated knowledge ever in the making but as historical ethnography of the operations of culture.

Abstract

Starting with a brief description of the essential features of functionalism in the social sciences, the article provides an overview of the major contributions to its development. Comte and Spencer shaped the origins of functionalism in the nineteenth century by conceptualizing society as an organism. Durkheim continued along this line in Sociology. Radcliff-Brown and Malinowski did so in Social Anthropology. Merton, Davis, Moore, and Parsons made functionalism the dominant paradigm of post–World War II sociology. Despite its decline in the 1960s, there has been a significant revival of the paradigm since the 1980s with neofunctionalism and Luhmann's systems theory.

Functionalism is a method of social science analysis, which has its roots in nineteenth-century social thought. It originated from the application of methods from biology, the rising science at that time, to the analysis of society. Three features are characteristic of this orientation toward biology: society is more or less strictly conceived as an organism; its development is understood as an evolutionary process; special attention is given to the relationship between the parts and the whole constituted by them, particularly to functions that have to be fulfilled by the parts for the working of the whole. The parts are institutions such as forms of family life, economic production, government, and religion as well as the organizational embodiments of such institutions: families, enterprises, governmental bodies, and churches. The institutions are binding rules, which regulate the activities and relationships between people. The functions are, for example, biological reproduction for the family, generating resources and allocating them to needs for economic production, binding decisions for the collectivity for the government, or the production of meaning for religion. It is assumed that, for its simple continuation, society needs the subserving of such functions by institutions and their organizational embodiments.

Origins of Functionalism: Auguste Comte and Herbert Spencer

It was the fundamental change from traditional agrarian to modern industrial society, which constituted the background for the rise of functionalism in nineteenth-century social thought, particularly in the work of Auguste Comte and Herbert Spencer. In his *Social Statics*, Comte conceived of society as a whole which, in its ideal state, is kept in perfect harmony by the balanced contribution of its constituent parts to its working in the process of fulfilling their specific functions. In his *Social Dynamics*, he conceptualized social change as an evolutionary process from lower to higher forms of societal organization. Because he expected science to bring about the perfect organization of social life in its final stage in modernity, he couched the evolutionary process in terms of the evolution of thinking from the theological to the metaphysical to the positive stage shaped by 'positive' science.

The other major source of functionalism in nineteenth-century social thought next to Comte is Herbert Spencer (1908). Though he shared the adoption of biological and evolutionary thought with Comte, he demarcated his approach explicitly from Comte's by conceiving society and social development not as a matter of ideas, but as a matter of objective things, namely, the behavior of human individuals. The major process in the development of society is differentiation; functions become more numerous and the tendency is that a function is fulfilled by one specific institution specialized in it. The more society grows in size, the more differentiated will be its functions and corresponding institutions. The first differentiation occurs between regulative, sustaining, and distributive functions. The corresponding institutions are government, economy, and the infrastructure of channels for transport and communication. With the differentiation of functions and institutions, society works like higher organisms, it becomes more heterogeneous, definite in the demarcation of institutions, and integrated; group life is transformed from the coexistence of groups with the same structure without coherence between them (families, clans) to greater heterogeneity but also greater coherence between groups. The evolution of social life goes from incoherent homogeneity to coherent heterogeneity in the process of specialization and growing division of labor.

The Classical Framing of Functionalism: Emile Durkheim

Among the great classical founders of sociology at the turn from the nineteenth to the twentieth century, it is Emile Durkheim (1893/1973a, 1895/1973b, 1912/1968) who made a distinctive contribution to functionalism as a method of sociological analysis. From Comte he borrowed the holistic view of society, from Spencer the idea that the growing division of labor is a core feature of social evolution. In his *Rules of the Sociological Method*, Durkheim made a clear distinction between functional and causal analysis and a clear statement that every functional analysis needs to be complemented by causal analysis. He argues that the utility of an institution in serving a need for individuals or in performing a function for society does not suffice to explain its existence.

In his study on *The Division of Labor in Society*, Durkheim points out that specialization and division of labor are tools for the self-preservation of the individual and the society and for integrating society. They help to overcome the struggle for scarce resources. This struggle is caused by the increasing material and dynamic density that results from population growth and the extending as well as denser weaving of ways and means of transport and communication. Nevertheless, serving self-preservation and social integration do not produce specialization and the division of labor by themselves. In Durkheim's eyes, this functional explanation of specialization and division of labor needs a complementation by causal analysis. In doing so, he looks for forces, which lead the selection of behavior and individuals in the direction of increasing labor division. He says that emigration, suicide, and crime would have been other possible solutions of the problem besides labor division. He explains the fact that they have not been selected to the same extent by the greater resistance called for by them. The bonds to one's home country work against emigration, the bonds to one's life against suicide, the sympathy for our fellows prevents us from committing a crime. They are on average stronger and more resistant feelings than the habits, which could prevent us from further specialization. The latter had to give way to the pressure toward specialization. In doing so, Durkheim points out the 'functional equivalents', which would serve self-preservation and then gives answers to the question as to the forces that lead human behavior in the direction of one of them. This is his complementation of functional analysis by causal explanation in his study on the division of labor.

In his later work on *The Elementary Forms of Religious Life*, Durkheim draws on anthropological studies on the Australian aborigines. Here he makes use of his idea of the circular link between cause and functional effect in the study of ritual practices in which the sacred is strengthened in distinction to the profane and in which the community is regularly becoming conscious of itself. We have a circular link here. People gather because they want to influence the demonic powers positively for practical reasons of a good harvest or hunt, their willingness to come together is, however, supported by their feeling of belongingness and solidarity, which is again strengthened by the ritual itself.

A Paradigm of Functional Analysis: Robert K. Merton

Durkheim's analysis of tribal societies was continued in the anthropological study of tribal societies, particularly by the leading British anthropologists, Alfred R. Raddcliffe-Brown and Bronislaw Malinowski. According to Malinowski (1948), every social phenomenon has to be explained by an indispensable function it fulfills not only for the whole of society, but also for the human individual: biological needs for food, shelter, and reproduction, psychological needs for support, needs for maintaining culture and social organization. Institutions of exchange, decision making, social control, and education should be explained by such functions. Radcliffe-Brown (1952) criticized Malinowski's emphatic functionalism and preferred to call his approach structuralism. He did not accept the presumption that every social phenomenon exists because of a necessary function it fulfills. In his view, the unity of society was not a postulate claimed for every society, but a hypothesis that allowed a functional explanation of a social phenomenon by its contribution to the persistence of society. One of his examples is the explanation of lineage systems by the fact that they help to avoid conflicts about property rights after the death of property holders and thus contribute to the maintenance of solidarity. It is obvious that such an explanation is nevertheless insufficient in the light of Durkheim's methodological objections against purely functional explanations.

At this point, it is quite reasonable to turn to the detailed methodological analysis of functionalism contributed by Robert K. Merton (1949/1968) in his paradigm of functional analysis. Merton points out three postulates of functionalism, which all have to be doubted in his eyes: (1) Functional unity postulates that society is one consistent whole and every phenomenon contributes to its working and that there is no division of society into parts with conflicting needs. (2) Universal functionalism postulates that every social phenomenon performs a positive function for the whole of society. (3) Functional indispensability postulates that every social phenomenon performs an indispensable function for the whole of society and cannot be replaced by some other phenomenon. Merton says that all three postulates are unfulfilled by concrete societies, particularly by modern societies, so that functional explanations of social phenomena cannot be based on them.

Instead, Merton introduced a more realistic paradigm of functional analysis with a set of 12 requirements: (1) Only standardized social phenomena like institutions should be analyzed with regard to their functions. (2) Subjective dispositions of actors and objective consequences of their action in social practices should be outlined and distinguished. (3) Positive, negative (dysfunctional), and neutral effects of standardized practices should be discerned. (4) The units for which an item fulfills a function have to be exactly determined. (5) The functional requirements for maintaining a system have to be denoted. (6) The mechanism of their fulfillment must be specified. (7) The functional alternatives have to be enumerated. (8) The structural context needs description regarding the narrowing down of space for functional alternatives. (9) Dysfunctions have to be detected and analyzed with regard to effecting stress and strain with resulting pressures for change. (10) The functional explanations should be validated in comparative research. (11) Functional analysis must be neutral in ideological terms. (12) Functional analysis of a social practice needs to include (a) the location of participants in the social structure; (b) alternative modes of behavior excluded by the pattern; (c) the emotive and cognitive meaning of the pattern for the participants; (d) a distinction between motivation and objective behavior; and (e) behavioral regularities that are part of the pattern but are not recognized by the participants.

A good example of Merton's idea is his functional explanation of the political machine by the various needs it fulfills for the whole of society and for a variety of groups. As an informal network with a boss at its head, it concentrates power and thus makes political decisions possible in the American political system of checks and balances; it also serves as a vehicle of helping the poor and weak, legitimate and

illegitimate business and provides channels for upward mobility. Thus the political machine becomes stabilized because – according to Merton's requirement – the positive functions outweigh the dysfunctions by far.

Functional Prerequisites and Social Stratification: Aberle et al. and Davis and Moore

In the 1940s and 1950s, functionalism achieved to the position of the dominant paradigm of sociological analysis under the name of "structural functionalism". The investigative strategy of structural functionalism was the discovery of the functions, which have to be fulfilled in order to secure the survival of society and the discovery of the corresponding structures serving these functions (Aberle et al., 1950/1967). Another representative contribution to structural functionalism is the functional theory of social stratification outlined by Kingsley Davis and Wilbert E. Moore (1945) in their much debated article 'Some Principles of Social Stratification' published in the *American Sociological Review*. Davis and Moore argue that every society needs a system of social stratification for the following reasons: (1) The members of the society share common views on the importance of a certain position needed for the provision of public and private goods and services. (2) To perform the corresponding roles, more or less talent, training and/or effort is required. (3) Thus, positions can be more or less important, the personnel needed for filling the positions more or less scarce. The greater the importance and scarcity, the greater the reward. The result is that positions are always stratified. The representative criticism of this functional theory of stratification was formulated by Melvin M. Tumin (1953) in an article published in the *American Sociological Review* 8 years later. It is couched in terms of conflict theory: The class structure is based on the power of the dominant class, which defines the importance of positions; its major effect is the differentiation of access to the higher positions according to socialization advantages and training of the offspring originating from the dominant class. Rather than contributing to the working and integration of society, the stratification system has disruptive effects so that society is not stabilized by value consensus and stratification, but by the application of power.

Functionalism as an Attempt at Synthesis: From Talcott Parsons' Structural Functionalism to Neofunctionalism

Five years earlier than Davis and Moore, in 1940, Talcott Parsons published another functional theory of social stratification, which he revised twice, in 1954 and 1975 (Parsons, 1954a,b, 1977). In the perspective developed by Parsons, social stratification has to be explained by the interaction of dynamic and controlling forces of action, interests and power on the one hand, and solidarities and cultural values on the other. Interests and power determine the access to positions and the enforcement of positional differences and outcomes, particularistic solidarities of family and lineage explain the inertia of class structures, because of the tendency of families to secure their offspring remaining in the same class position. The *legitimacy* of the stratification system in distinction to its factual production and reproduction is, however, an effect of the consensus on a grading scale according to which prestige is attributed to positions. Only in as much as such a consensus on a grading scale is achieved will the system of stratification be accepted as legitimate. Otherwise, the definition of the importance of positions and the access to them will be a matter of the war of all against all. In general terms, this is the problem of double contingency.

Other than Merton's deliberate plea for empirical middle range theories, Parsons' program was analytical grand theory. Merton stood for empirical functionalism, Parsons for analytical functionalism (Parsons, 1951). He introduced his four-function paradigm as an analytical instrument of analyzing structures as well as dynamic processes with regard to abstract functions (Parsons, 1966, 1967, 1978; Parsons and Smelser, 1956). By cross tabulating the instrumental/consummatory and the internal/external orientation of action, he defined four abstract functions: instrumental/external: adaptation (A), consummatory/external: goal attainment (G), consummatory/internal: integration (I), and instrumental/internal: latent pattern maintenance (L). For further differentiation, Parsons distinguishes three levels of applying the four-function scheme: (1) social system: economic (A), political (G), community (I), and fiduciary (L) system; (2) general action system: behavioral (A), personality (G), social (I), and cultural (L) system; and (3) human condition: physicochemical (A), organic (G), action (I), and telic (L) system. Further differentiation results from the application of the scheme to one of the subsystems. After having developed an analytical action theory in his first work of 1937, *The Structure of Social Action* (Parsons, 1937/1968), Parsons established structural functionalism as a link between analytical functionalism and systems theory in *The Social System* in the early 1950s, and extended that link with the introduction of his theory of generalized media of interchange (money (A), political power (G), influence (I), and value commitments (L) for the social system) and his theory of evolution as instruments for the analysis of dynamic processes of inflation and deflation and social change in the 1960s. With his turn to functionalism, systems, media and evolutionary theory he did, however, not give up the core position of his early action theory: the idea that social order emerges from the interaction between controlling and dynamizing forces. In his systems theory, he couched this idea in the double cybernetic hierarchy of conditions and controls. From (L) to (A) energy and dynamics in the system increase, while information and control decrease, and vice versa.

Looking at one analytical level, the social system, this system is composed of subsystems, which fulfill their specific functions (A G I L) with specific structures (markets (A), authority (G), association (I), and communication (L)) and specific media of interchange. They build an interrelated set of systems with in- and output processes of factors and products processed by the circulation of the media from one system to the other (interpenetration). Crises in the working of the systems can be analyzed as inflation–deflation spirals of the media involved.

In his theory of evolution, Parsons tries to point out the evolutionary advantage of specific institutions. Religion, communication by language, social organization through kinship and technology are the first conditions of building human societies. A breakthrough to higher forms of social organization is realized by social stratification according to prestige based on achievement instead of ascription by origin. The rigidity of kinship systems is pushed back in this way. A further step forward is the replacement of tradition by cultural legitimation through general values. The developmental stage of a modern society is realized by the establishment of bureaucratic organizations, markets and money, universalistic norms and democratic association. In two volumes, he outlines the evolutionary process in four dimensions according to his AGIL scheme: adaptive upgrading (A), structural differentiation (G), inclusion (I), and value generalization (L).

Evolutionary achievements require breakthroughs in all four dimensions. He points out such breakthroughs in his analysis of primitive societies, archaic societies (Egypt and Mesopotamia), intermediate historic empires (China, India, Islamic, and Roman empires), seedbed societies (Israel, Greece), and, finally, the system of modern societies from ancient cultural roots via the Renaissance and the Reformation to the Enlightenment and the building of modern citizenship, state and capitalism. The major modern breakthroughs are the industrial, the democratic, the educational, and eventually the 'expressive' revolution of the 1960s and 1970s (Parsons, 1966, 1967, 1971).

According to his position that social order always has to reside in some form of consensus and solidarity in order to avoid an unlimited power struggle, Parsons lays special emphasis on the development of citizenship as a core of a modern 'societal community'. It is a modern form of community, which has the greatest potential for inclusion, it associates people of the most varied ethnic and cultural origins. In this respect, it is the cornerstone of modern social organization. He sees the society of the United States farther developed in this respect than the ethnically more homogeneous European welfare states (Parsons, 2007). The modern community of citizens is the core, which is complemented by a capitalist economy; democratic government; and universalistic institutions of education, science, professional work, and voluntary religious association. This is the abstract path of sociocultural evolution, which has to be distinguished from concrete historical development that can more or less deviate from this path. There is particularly always the danger of fundamentalist movements against modernity, which originate from the severe tensions caused by the evolution of modern forms of social organization. For Parsons, fascism as well as communism were such fundamentalist reactions to modernity, which have, however, no chance of long-enduring stabilization in his eyes. Therefore, he expected that the Soviet system would crumble some time, an expectation grounded in 'abstract' evolutionary theory, which turned out to be very 'realistic' eventually.

Criticism of Functionalism

The dominant role of functionalism during the 1950s and into the 1960s provoked criticism pointing out its weaknesses and aiming at new approaches to study society. In the 1950s already, Lewis Coser (1956) and Ralf Dahrendorf (1958a,b) objected to functionalism with regard to its inadequate understanding of social conflict. Drawing on Georg Simmel, Coser emphasized that social conflict is not only disruptive in its effects, but – under certain specific conditions – also meets functions of maintaining social relations and integrating society. He developed a kind of conflict functionalism. There are conditions that mitigate conflicts such as chances of expressing frustration openly, a greater number of alternatives for action, little frustration before a conflict becomes evident, exclusion of emotional and ideological motives, and a focus on the substantial objects of conflict and stable social relations. External conflicts with other groups strengthen the groups' identity and cohesion, but also coerce nonconforming members of the group. Also, external conflicts contribute to stabilizing and strengthening relations between the conflicting individuals or groups.

Ralf Dahrendorf criticized functionalism's one-sided focus on consensus, social integration and social stability. He did not want to abandon the functionalist view of society, but wanted to complement it with a special emphasis on constraint, conflict, and change. As he puts it, functionalism considers society as a relatively stable and well integrated configuration of elements, all of which contribute to its functioning, while society is founded on consensus. From the complementary point of view of conflict theory, society is based on the constraint exercised by some of its members on the other members, and it is in continuous change entailing always conflict. All its elements contribute to its change. George Homans (1961, 1964) challenged functionalism's holistic approach to study society and to focus on institutions, structures, and functions of the society at large and the corresponding search for "grand theory" with a plea for methodological individualism. He argued for "bringing men back in" and for a sociological explanation based on psychological laws that he derived from behavioristic learning psychology. Any explanation of social institutions and social change is required to trace them back to the actions of human individuals. For example, the stability or change of an institution like the appearing of students in class at 8 a.m. every morning of a school day resides in the students' motivation to appear or not appear in class at that time every morning of a school day. Homans initiated a kind of micro-sociological revolution against functionalism (Alexander, 1987: pp. 156–280). Besides Homans' psychologically based theory of human behavior, other parts of this revolution included symbolic interactionism as it was advanced by Herbert Blumer (1969) based on George Herbert Mead's social behaviorism; Erving Goffman's dramaturgical theory of interpersonal communication; and Harold Garfinkel's studies in ethnomethodology. These approaches were addressing the construction of social order in social interaction. They all shared Denis Wrong's (1961) criticism of Parsons' "oversocialized conception of man". Wrong emphasized that members of social groups, communities, organizations or societies are not completely socialized to the extent that their action is nothing but role-taking and conformity to norms and role expectations. Socialization itself is

a conflictual process and is incomplete so that there is always space for deviation from established norms and for change of social order. From the point of view of symbolic interactionism, any social order is not given once and for all, but has to be negotiated and renegotiated time and again in everyday interaction (Strauss, 1978).

From the macro-sociological perspective, it was first of all C. Wright Mills (1956, 1959) who challenged what the critiques called functionalism's preoccupation with consensus, order and stability and the understanding of society as a widely harmonious whole composed of interdependent parts that all contribute to its functioning. From Mills' point of view, this preoccupation with consensus, order and stability made functionalists unable to address power, conflict and constraint in a realistic way. This was particularly true for the functionalist perspective on American society. As Mills elaborated in his widely received study *The Power Elite*, American society underwent a major change after World War II and in the wake of the Cold War between East and West. Up to that time, the business elite was most influential in shaping society and politics. With the Cold War, the federal government's leadership became more important along with the military leaders. Mills saw American society widely ruled by what he called the military–industrial complex, that is a close network of leaders from military and big business and their involvement in the federal government. In Parsons' (1960: pp. 206–247) eyes, Mills exaggerated the connections between military, business, and government and underestimated the functional differentiation of society. For Parsons, military, business, and government fulfill specific functions for society. Their leaders play a crucial role in meeting these functions, but do not unite in a closed elite that rules society in its particularistic interest.

Here is the crucial point at which Alvin Gouldner's (1970) critique of Parsonian functionalism set in. While the critiques mentioned so far were directed against functionalism in a still dominating position, Gouldner launched his criticism at a time at which the decline of the paradigm was well under way. His book *The Coming Crisis of Western Sociology* was written as an account of this decline and put forward a plea for a reflexive and a radical sociology. Gouldner elaborated the similarity of Parsonian functionalism to Plato's philosophy of a partially good world, which can be improved by moving toward an ideal order where every part of it is in equilibrium with all other parts and contributes to the functioning of the whole. Society is a whole composed of interdependent parts that all contribute to its functioning. By looking at society in this way, functionalism is conservative in the same way as Plato's philosophy was. That means, even if it does not directly aim at conserving a concretely existing society and its institutions, it has to look at it in a way so that practices and institutions are identified in their functional contribution to society and its order. Even if problematical phenomena can always be observed in society, they can only be conceived as deficient, which calls for improvement in order to meet the required function for society. Thus the functionalist perspective may see deviance, conflict, and disorganization in society but will never open the observer's eyes for the deeper causes of these phenomena and will always search for remedies that help to improve given institutions so that the existing society arrives a better shape and greater balance. This conservatism inherent in functionalism implies its adaptation to society as it exists. It may fulfill this conservative 'function' in a liberal capitalist society, in a society characterized by capitalism's embeddedness in democracy and welfare institutions and even a socialist society. Against this conservative character of functionalism, Gouldner argues for a reflexive sociology that reveals the deeper roots of contemporary tensions and conflicts in society and a radical sociology that opens up ways toward a more profound change of society and toward a better future.

Marxism became a major stream of radical sociology in the 1970s. The revitalization of Marxism at that time entailed, however, a remarkable bloom of functionalist thinking in its broader terms. Social theory inspired by Marx had to find an answer to the question as to why capitalism did not break down in the West as postulated by Marx in his study on the rise and future decline of capitalism. The widespread answer to this question was the rise of stabilizing institutions like science and technology, social partnership between industrial federations and trade unions and government interventions in the economy aiming at minimizing its disruptive effects. It was Jon Elster (1982) who addressed exactly this turn of Marxism to a kind of functionalist method of analysis. Elster referred to the logical incorrectness of functionalist explanations as already identified by Carl G. Hempel from a methodological point of view. As he emphasized, it is logically impossible to explain the existence or rise of an institution by the function it fulfills for society. Against the preoccupation of functionalism with methodological holism – the whole is more than its constituent parts – he argued in favor of methodological individualism. The emergence and existence of institutions have to be explained by the motives and actions of the major actors who have created them or are maintaining them even against resistance at a certain time in history. Elster identifies Christian theodicies as a major root of functionalism reaching their summit in Leibniz's teaching that everything happening in this world will end up as good for the human individual. For him, Bernhard de Mandeville's teaching that private vices produce public benefits constitutes a secular version of Christian theodicy. Adam Smith's statement that some invisible hand turns private utility maximization into public wealth on the market also belongs to this category of functionalist reasoning. Elster considers this type of reasoning as a weak functional paradigm which assumes that some behavioral pattern has beneficial consequences for some social unit, but is unintended and not recognized as such by the beneficiaries (Elster, 1982: p. 454). Elster also identifies a main functional paradigm that explains the existence of an institution or behavioral pattern by referring to their latent functions for a social unit, and a strong functional paradigm, which assumes that all institutions and behavioral patterns can be explained by a function they fulfill for a social unit. Elster supplies a variety of examples for these types of functional explanations in the social sciences, particularly in Marxism. They all share the assumption of some objective teleology in social processes such as Hegel's idea that history develops dialectically in the

direction of reality coming closer to reason, that means the real turns out to be the reasonable. Elster gives a variety of examples of this kind of functionalist reasoning and he shows that not only functionalism in mainstream sociology adheres to this type of reasoning, but also, very broadly, Marxism from its very beginning in Marx's writings themselves through to the renewal of Marxism in the 1970s in particular. One example is Marx's explanation of the Bonapartist regime that deprives the bourgeoisie of exerting political power directly in order to protect it from self-destruction so that it maintains its dominant position in society in the long run (Elster, 1982: p. 458). Elster demonstrates furthermore that many Marxist analyses explain what exists by its function for maintaining capitalism and serving the capitalist class. The state in whatever form it may exist is explained by its function for capitalism and the capitalist class. As Elster points out, all these functional explanations are deeply flawed, as they simply cannot explain what they want to explain. There are always functional alternatives and the attributed function for a social unit does not bring about an institution or behavioral pattern by itself. For Elster, there is no other way than looking at the actors and their motives in creating and maintaining institutions and behavioral patterns. This is what methodological individualism requires from sociological explanation.

Functionalism and Modern Systems Theory

The dominant role played by Parsonian functionalism in the 1950s provoked counter-movements, which concentrated mostly on some particular aspect of social organization, which was relativized within the very general Parsonian scheme. The need for revitalizing the Parsonian approach has indeed called for a new movement, which aims at continuing with the general program of Parsons on the contemporary level of development. This is the movement of neo-functionalism, which arose in the 1980s. Neofunctionalism tries to advance the Parsonian legacy by way of learning from new developments in social theory and social research, for example from advancements provided by Clifford Geertz or Jürgen Habermas. This new movement has contributed fresh interpretations of Parsons' work along with a new reading of the classics, studies on civil society and public discourse, on the evolution of the culture of modernity, on communication society, European integration and globalization (Alexander, 1982/83, 1998, 2006; Münch, 2010, 1987/2011, 2012).

A comprehensive renewal of functionalism has been undertaken by Niklas Luhmann (1970, 1984, 1997). He, too, combines functionalism with systems, media, and evolutionary theory. In his early phase of theory-building, Luhmann introduced a turn from structural-functional to functional-structural systems theory. To justify this turn, he claims that the question of function has to be posed in a more fundamental way. Before we ask for the structures of systems, which have to fulfill certain functions, we should raise the question as to which function is served by systems building as such. What is the problem solved by systems building? This is how he asks his question. His answer is: world complexity, which needs reduction so that it can be handled. Systems just perform this function of reducing world complexity.

In his second phase of theory building, Luhmann undertook another turn of his functionalist systems theory: the conceptualization of social systems as autopoietic, self-referential systems. Because there is always the danger of too much complexity, the major problem is systems building and the continued maintenance of systems boundaries, which are boundaries of meaning. Autopoiesis is a form of systemic operation, which guarantees the maintenance of boundaries and, at the same time, allows for maximum absorption of environmental complexity. An autopoietic system is operationally closed, but open to any kind of complexity in the environment. Operational closure is guaranteed by a binary code according to which any kind of environmental complexity is processed. The concrete processing is organized by a system's program. Special links to other systems in the environment are stabilized by structural coupling. Generalized media of communication allow for most flexible forms of systemic processing: money, power, law, and love, for example. Social systems are built up by communication, they originate from that and continue to exist as long as communication takes place according to the established code. Communication consists of three elements: information, message, and interpretation.

An autopoietic system produces and reproduces all its elements – communication – by itself, i.e., by systemic communication, but it makes use of environmental complexity. It does not take inputs from the environment to transform them into outputs, but receives impulses from the environment to which it shows more or less response. The system observes events in the environment and absorbs them according to its own code and program. Problems of maladaptation to the environment can be discovered by second-order observation, which is self-observation and self-description.

Luhmann distinguishes three levels of social systems: interaction systems, organizational systems, and societal systems. According to his theory of evolution, more complex societal systems evolve by variation, selection, and stabilization. There are three (later: four) stages of societal evolution, which are defined by the form of differentiation of systems: segmentary, estate (later: center/periphery), and functional differentiation.

Modern societies are functionally differentiated and no longer have a center. The economic, political, legal, science, educational, and arts systems are more and more differentiated on a world scale and thus transcend their centering around a societal community and/or a state. Thus the nation-state societies are transitional stages on the way to world society. Paying vs. not paying, having power vs. having no power, right vs. wrong, true vs. false are the binary codes of the economy, polity, law, and science systems. The evolutionary process works toward the establishment of functionally differentiated systems on a world scale, which are linked by structural coupling and by mutually stabilizing coevolution.

Niklas Luhmann's systems theory attracted great interest, particularly in the 1970 and 1980s, and above all in Germany. Many younger sociologists adopted his paradigm of autopoietically operating systems. Also, he provoked some

controversy as to the best approach to social theory. It was Jürgen Habermas, working in the tradition of critical theory, who launched the most thoroughgoing criticism against systems theory in his critique of functionalist reason. He borrowed from Parsons's and Luhmann's works to construct a twofold social theory, a theory of communicative action that focused on the interaction between systems and life-world (Habermas, 1981). In reference to Marx's concept of alienation in modern capitalism, he developed the thesis of the colonization of the life-world of communicative relationships between people by the systems of economy, politics, bureaucracy and law.

Future Need for Functionalism

The question finally is: What will be the future of functionalism after its renewal by neofunctionalism and by Luhmann's functionalist systems theory? Whatever the movements against functionalism have contributed to our knowledge, we cannot say that they can replace the insights of functionalism completely. They have merely emphasized some particular aspect of social reality and some particular question. But they did neither raise nor answer the questions posed by functionalism from Comte and Spencer to Parsons and Luhmann. Because their questions are still legitimate, there is still a place for functionalist theorizing, whatever form it might take in the future.

Abstract

The World Health Organization's *International Classification of Functioning, Disability and Health* (ICF) constitutes a shift in how we understand and as a society respond to disability. Conceptually, the ICF embodies an integrative understanding of the universal human experience of disability and as a practical tool it provides a multidimensional classification and standard language for health information. We focus here on the conceptual framework of the ICF as well as its classificatory structure and health applications before considering issues and applications particularly relevant to the social and behavioral sciences that are. We also contrast ICF George Engel's 'biopsychosocial' model and ICF's role in operationalizing health.

Introduction

The endorsement of World Health Organization's International Classification of Functioning, Disability and Health (ICF) (WHO, 2001) by the 54th World Health Assembly in 2001 represented both a deeply conceptual and practically significant advance for natural, social, behavioral sciences in the conceptualization, description, and assessment of human functioning and disability. Conceptually, the advance arises from a person–environment interaction model, termed as the 'biopsychosocial model,' upon which the ICF is based. This model avoids sociological and biomedical reductionisms and provides a starting point for a comprehensive and integrative understanding of the universal human experience of functioning and disability, and by extension the experience of health itself (Cieza et al., 2008). Practically, the ICF provides a multidimensional classification that constitutes both an international standard language of functioning and disability, and the ontology of a systematic description of the total health experience.

In this article, we will first focus on the conceptual framework, or model, of the ICF before moving on to details of its classificatory structure. That will be followed by a brief review of the potential uses of the ICF within the health sciences, broadly construed, and conclude with a discussion of the range of applications that are particularly relevant to the social and behavioral sciences. Along the way, and to avoid a natural confusion, we will contrast the ICF model with George Engel's influential, and similarly named biopsychosocial model (Engel, 1977). We will also explore the potential for the ICF – both as a conceptual model and a classification of functioning – to provide a much-needed operationalization of the contentious notion of health.

The ICF Biopsychosocial Integrative Model

For more than 40 years models of disability have proliferated, shedding more heat than light (for overviews see Shakespeare, 2006; Bickenbach, 2012). The debate, part science and part politics, has pitted the 'medical model' against 'the social model' – the first purportedly reducing disability to biomedical facts, the second reducing it to the social construction of a marginalized and stigmatized subpopulation. The developers of the ICF sought to avoid both extremes, without abandoning what is valuable in each position. The resulting model implemented the following interlocking principles:

First, disability should be understood as a universal feature of humanity, not the mark of a minority population. Disability is not some 'special' attribute that some people possess and others lack: at bottom disability arises from the blunt fact that human life arises out of a myriad of biological functions that are, in the end of the day, both fragile and susceptible to less-than-optimal levels of functioning – either congenitally, or because of disease, disorder or injury at some point in life. Aging itself is a matter of a progressive decline in biological functions – yet another reason to see disability as a normal feature of living. From a policy perspective, the universality of disability, as the disability sociologist Irving Zola recognized 25 years ago, 'demystifies the specialness of disability,' opening the door to mainstreaming disability across all sectors of society (Zola, 1989).

Disability is universal for another important reason. All biological functions, and the vast number of human actions and behaviors that they make possible, are continuous not dichotomous phenomenon. Each biological function operates in the domain of 'more or less' not 'all or nothing.' Although some manifestations of disability are total – blindness, for example – most are a matter of degree. Where on this continuum between 'complete' functioning and 'total lack' of functioning constitutes a problem (termed in the ICF, an impairment) is a matter of judgment and susceptible to a wide range of considerations, both personal and social. As a consequence, the ICF is principally a classification of functioning and only derivatively of problems or decrements of functioning, that is, disability.

Finally, the experience of disability depends, not merely on biological functions and their impact on the actions and behaviors that people can perform, but also and crucially on the total context in which people live. That is, functioning and disability are outcomes of an interaction between intrinsic features of people (usually expressed in language of biology and psychology) and the physical, human-built, attitudinal, social, political, economic, and cultural environment in which people

live. In particular, disability arises from both biology and the physical and social world. And again, the point at which the operation of a biological function becomes problematic for an individual will depend both on what the person wants to do or behave and what is possible given the person's environment, what is required or expected to do or behave.

To fully operationalize the principles of universality, continuity, and interaction, the ICF 'biopsychosocial model' is constructed in terms of three dimensions of functioning: body functions and structures, activities, and participation. Problems or difficulties in these dimensions are termed impairments, activity limitations, and participation restrictions. For terminological consistency, a decision was made to jointly call these three negative dimensions 'disability.' To complete the model, the two primary categories of determinants of disability are added. First, the underlying health condition (understood as a health state that yields problems of functioning, that is, diseases, disorders, and injuries), and secondly, contextual factors of environmental and personal factors (the latter only mentioned and left for further development). The environmental factors component reflect the long-accepted account of health as being, at least in part, determined by underlying physical and social determinants (cf Whitehead et al., 2003). Diagrammatically, the ICF model is represented in Figure 1.

As an example, an individual who has incurred a spinal cord injury will, as a result, experience a range of impairments of body function and structure, including lower body paralysis, loss of bowel and bladder control, and muscle wasting. These and other impairments will directly affect the person's physical capacity to perform a variety of simple and complex activities, including walking and managing excretion, and may well affect other very complex social activities such as making friends or pursuing education or employment. These activities and tasks, however, can be ameliorated to one degree or another by changes to the person's environment that can facilitate activities and participation. The most obvious is the provision of a wheelchair and other assistive devices. Less obvious, but often more consequential, are alterations to the physical environment of the school or place of employment (in the form of elevators, adjustable desks, personal assistance, and so on). These facilitators enable the individual to carry out the appropriate complex tasks. Finally, less obvious still, but also highly significant, are those social, cultural, and political environment changes that either remove attitudinal or cultural barriers such as stigma and discrimination, or else effect those political changes that ensure full social inclusion.

Figure 1 The model of functioning and disability on which the ICF is based.

Other health conditions and impairments will yield a very different portrait of the disability experience. For contrast, think of mental health conditions in which the impact of attitudinal environments, in the form of stigma, fear, and misunderstanding, can be far more determinative of limitations in social participation than the underlying health condition itself. People with noticeably aberrant or nonstandard behaviors – from simple facial tics and spasms to complex forms of antisocial behavior – may be more limited (and hence, more disabled) by their social environment than by their impairments. Yet, some mental health problems such as depression and extreme forms of dementia can rarely be ameliorated by environmental facilitators (other than, perhaps, medication) and are more dramatically determined by the underlying health condition and resulting impairments.

Significantly, each dimension of disability is associated with a range of appropriate social responses or interventions. At the level of impairment, medical or rehabilitative responses are the most appropriate, and in this sense, the 'medical model' is an accurate, though partial, representation of the disability experience. At the person level of activity limitations – operationally identified by assessing a person's capacity to perform activities in a given or standardize environment – the appropriate responses will either aim to increase inherent capacity levels, or else designed assistive technology that augments capacity suitable for actual contexts or environments appropriate to the individual's needs. Finally, at the level of the person-in-context, the paradigmatic interventions are those that either remove environmental barriers to full participation or else put into place environmental facilitators, or both. At this, the most complete level of experience, the appropriate interventions should be conceived as including, not merely the physical, organizational, and attitudinal environmental alteration, but also all of the social and political antecedents needed to bring about these environment change: research, political mobilization and lobbying, legal change, resource allocation, policy creation and implementation, and so on. This is true whether the environmental alteration involves putting in curb cuts for greater wheelchair mobility, or instituting a policy of positive action in public-sector hiring.

The ICF conceptualization of functioning and disability identifies both underlying impairments and the overall context or environment in which the person lives as coequal determinants, with the precise configuration of influences being identifiable on a case by case basis. Unlike both the social and the medical models, the ICF provides no account of how disability comes about in general, but offers a relatively theory-neutral descriptive model that is a template for explanation. If a researcher wishes to show that, say of an instance of employment restrictions for people with mobility problems, this is primarily the product of social prejudice, or unaccommodating workplace environments, or the underlying impairment, the researcher can rely on the ICF to collect relevant evidence to make the case. In short, the ICF's biopsychosocial model rejects both the medical and the social model are reductively distorting, while preserving the germ of truth contained in each.

Comparing the ICF Model with Engel's Biopsychosocial Model

Because of the similarity in the label, it is tempting to compare the ICF 'biopsychosocial model of functioning and disability' with the approach famously offered up in 1977 by psychiatrist George Engel. As it happens, the similarity between the two models ends with the common label, and it is instructive to see why this is so.

In his 1977 presentation of his model, Engel's concern was to "provide a basis for understanding the determinants of disease and arriving at rational treatments and patterns of health care" (Engel, 1977, p. 196). His critique of the 'biomedical model of disease' was in part conceptual – rejecting its reductivism and tendency to dismiss nonbiomedical explanations as irrelevant – but was for the most part clinical or therapeutic. His biopsychosocial model was a plea for the scientific legitimacy of investigating nonbiological, or what we now call social determinants of disease (see **Figure 2**); yet all of his arguments focus on the single, purely clinical phenomena that patients seek medical help not merely because of experienced biological dysfunction, but also because of expectations about what it means to be healthy, expectations that are socially, culturally, and even linguistically, determined.

At one point, he argues that, biomedically, the state of grief has all the hallmarks of a disease – bodily and psychological disturbances and a predictable symptomatology and prognosis. But, significantly, grief is rarely so perceived because, socially and culturally, it is understood as a 'problem of living' not a disease. In short, patients acknowledge diseases only if they perceive them as sickness, and they will only do so within the framework provided by psychological and cultural expectations. The physician, Engel concludes, must therefore supplement her or his biomedical knowledge, with skill in social and psychological perceptiveness in all therapeutic encounters.

By contrast, the ICF does not offer any account of the determinants of disease or other health conditions, and for this reason alone the two models are radically different. But in addition, the ICF does not make any distinction between health states and the perception or feeling of being 'sick.' The ICF is a wholly objective, descriptive tool. Of course, it is evident that a person can have a disease and not feel sick, or feel sick and be perfectly healthy: this is a crucially important clinical realization that, as Engel argued, a responsible physician needs to take on board. But the distinction between health and sickness is irrelevant for the description of health states and the dimensions of functioning that can, in interaction with environmental factors, led to disability. Description, as a precondition for assessment and measurement, is the raison d'etre of the ICF.

Finally, it is not entirely accurate to say that the ICF utilizes a biopsychosocial model at all, at least one that bears a family resemblance to Engel's model of determinants of disease. In fact, although many of the environmental factors are social phenomena, many if not most environmental factors are physical things in the world – weather, buildings, elevators, and other people. It might have been better to use the terminology now becoming more common in the disability literature and naming the ICF model the 'environmental' or 'interactive' model.

Understanding Health in Light of the ICF

Conceptually, how might the ICF assist in our understanding of health? Needless to say, health is a highly contested notion, even though we have an intuitive grasp of what health is or at least what it means to us. The technical, philosophical debate over the definition of health – fluctuating between purely descriptive and biological conceptions (e.g., Boorse, 1975, 1977) to normative accounts linking, or equating, health with well-being (e.g., Nordenfeld, 1987) – is inconclusive. WHO's famous 1948 definition of health as "a state of complete physical, mental and social well-being and not

Figure 2 Engel's model as depicted by Albery and Munafò (2008) is presented in the upper part. The mentioned psychosocial factors represent the determinants of a health condition. The ICF biopsychosocial model is presented in the lower part.

merely the absence of disease or infirmity" has been roundly criticized (e.g., Calahan, 1973) for being utterly resistant to scientific application. Yet, though WHO has never abandon its aspirational definition, in more technical papers it has responded to the need for a basis for quantifying health, without which not even the first steps in clinical quality assurance, basic epidemiology, or the evaluation of public health strategies could be taken. This approach relies on the ICF notion of functioning.

In 2003, WHO offer a conceptual of health 'for measurement purposes' that built on the following intuitions (Salomon et al., 2003):

- Health is a separate concept from well-being, although it is of intrinsic value to human beings and instrumentally linked to other components of well-being.
- Health is comprised of states or conditions of the human body and mind, and therefore any attempt to measure health must include measures of body and mind functions.
- Health is an attribute of an individual person, although aggregate measures of health may be used to describe populations.

The second intuition is fundamental, and reflects the influence of the ICF: at bottom health is a matter of the operation of body functions and structures, simple and complex. It may be that we need to posit central human goals and values in order to characterize the state of 'good health' (e.g., as Nordenfelt, 1987 argues). And we may need a broader notion of health that includes the performance of highly complex and social-constructed activities such as are require for community life, education, or employment (Daniels, 2007). But, as at the end of the day if health is not rooted in functions and structures of the body and mind, then the notion arguably lacks scientific or practical usefulness. This, indeed, is the underlying implication of the ICF model, and in this sense the ICF can be viewed as providing an operationalization of the concept of health, if not in general, then at least for scientific purposes (see Cieza et al., 2008).

The ICF Classifications and Health Information

The ICF is more than its conceptual framework, of course. Essentially, it is an epidemiology standard instrument, a classification. Certainly, WHO's own interest in developing and promulgating the ICF is to fulfill its constitutional mandate to provide the world with comparable health information. WHO's more well-known information standard classification, International Statistical Classification of Diseases and Related Health Problems (ICD-10) (WHO, 1992), currently under revision, is used worldwide to report causes of death for mortality statistics. Though essential for measuring life expectancy, ICD data did not capture the overall health status of living populations. Missing was information about nonfatal health outcomes, that is levels of functioning and disability across all areas of life. The ICF was therefore developed in order for standardized information about living with a state health, or as it is sometimes put, the lived experience of health. This information is proving to be essential as studies indicate that diagnosis alone does not predict health service needs, length of hospitalization, or level of care required. Nor is the presence of a disease or disorder an accurate predictor of receipt of disability benefits, work performance, return to work potential, or likelihood of social integration. With the decrease in significance of infectious diseases and the burgeoning impact of population aging and the increasing prevalence of chronic health conditions, including those like mental health problems that do not shorten life, it was clear that for nearly all epidemiological, health systems and clinical care research, what is required was information about functioning and disability.

As a practical tool, therefore, the ICF is designed to capture the information needed, at the individual and population level, to fully comprehend the experience of health, including the ramifications for functioning and disability. To accomplish this, the ICF is composed of three classifications: a classification of body functions and structures, a classification of domains of activity and participation, and a classification of environmental factors. The 'words' of the ICF standard language are called ICF categories. The ICF contains a total of 1454 ICF categories: 493 body functions, 310 body structures, 393 activities and participation domains, and 258 environmental factors. These categories are hierarchically organized in chapters with progressively detailed specification. ICF chapters represent the first level of the hierarchy and the first frame of reference for capturing health information. Each chapter is then decomposed into more detailed second-level categories, which in turn are decomposed into third- and fourth-level categories. For example, the following is the structure of the first chapter of Body Functions:

'b1	Mental functions'	(first/chapter level)
'b114	Orientation functions'	(second level)
'b1142	Orientation to person'	(third level)
'b11420	Orientation to self'	(fourth level).

The overall structure of the components of the ICF classification is represented in **Figure 3**.

To capture the severity of an impairment, limitation, or restriction, the ICF includes a general or generic qualifier with a simple rating scale of five response options: 0 = no impairment (limitation or restriction), 1 = mild, 2 = moderate, 3 = severe, and 4 = complete impairment (limitation or restriction). In the case of environmental factors, the qualifier captures the extent to which an environmental factor is a facilitator or a barrier, with a total of nine response options ranging from +4 (complete facilitator) to −4 (complete barrier), with a 0 value indicating neither a facilitator nor a barrier. Although strictly speaking, the ICF is not an assessment tool but a descriptive classification – a classification of 'what to measure' not a guide to 'how to measure' – the use of qualifiers provider, a rough guide to the extent or severity of category being used. In practice, existing assessment instruments or patient-reported outcomes can be mapped onto the values of the ICF categorical coding so that information collected by these instruments can then be compared by means of the standardization that the ICF provides.

Given WHO's motivation for developing the ICF, most of the current uses of ICF are geared to serve the requirements

Figure 3 The structure of the ICF.

of epidemiology and health information systems. Given the enormous number of health and functioning assessment tools – both generic and health condition-specific – that are currently in use (McDowell, 2006), the ICF has become an essential comparative standard (a kind of Rosetta stone) for linking information collected using different instruments and in different health and rehabilitation settings. At the highest population level, ICF can be similarly used to compare data collected from population health or disability surveys at the national level, for, ultimately, more valid and reliable data on prevalence and incidence. Given the huge range of operationalization of disability used in such surveys around the globe, the ICF is only available standard language for international comparable statistics (WHO, 2011, Chapter 2).

At the level of clinical practice, the ICF is increasingly being used as a reference framework and classification for the development of clinical assessment and measurement instruments (Rauch et al., 2008). Further steps toward a wider clinical application of ICF is the development of condition-specific and generic 'core sets' of ICF categories that identify those categories that are necessary and sufficient for clinical description of condition and treatment setting (see, e.g., Biering-Sorensen et al., 2006), as well as 'linking rules' that enable a direct translation between existing clinical terms and ICF categories (Cieza et al., 2005). Although there is still work to be done to fulfill the measurement potential of ICF, which in part depends on the development of interval scales for particular ICF categories, based on existing clinical test batteries and patient-orient instruments, significant progress is being made in this direction (Stucki et al., 2008). Finally, ICF has also proven to be a useful basis for patient education programming (Neubert et al., 2011).

Applications of ICF to the Social and Behavioral Sciences

Because of WHO's original motivation for developing the ICF, and its health information applications, most of the applications of the ICF found in the literature focus on population health and clinical information applications, including assessment instrumentation, principally in fields of rehabilitation (see Mpofu and Oakland, 2010). Limit work has been done in the application of ICF in psychology (Peterson, 2011), but the full potential value of the ICF in this area has yet to be surveyed. Given that most of the literature on the 'models of disability' has been firmly rooted in central sociological and social psychological traditions seeking to theorize deviance, stigma, and minority status, it is somewhat surprising that the ICF has generally been received with indifference. It is undoubtedly true that, given its providence, the ICF can easily be dismissed as a classification by and for health scientists and epidemiologists. But that would be unfortunate since there are at least three themes embedded in the ICF that have significance far outside the health sphere, and would benefit from closer scrutiny by social scientists.

Understanding Environmental Factors

Environmental factors in the ICF are determinants of disabilities, coequal in significance with health conditions. Two individuals with precisely the same health condition, and impairments, may experience vastly different restrictions in the lives because of features of their physical and social environment: one may be able to be fully employed because of workplace accommodations; the other may face such significant social stigma that he or she is housebound. The presence of facilitators and barriers shape individual lives and the experience of disability. Yet, other than the easy cases of the provision of assistive technology and accommodations, or social exclusion and discrimination, we know very little about how environmental factors interact with health states to yield decrements in functioning. The ICF provides the vocabulary for describing these factors, but the science and instrumentation needed to assess and measure this impact is, at best, in its infancy.

To be sure, occupational and physical therapists have long appreciated the need for exact description of environmental impact since many of their interventions depend on it. Yet, while their knowledge about the direct or immediate physical

environment of assistive technology and physical accommodations may be well developed, the impact, positive or negative, of other domains of the environment are far less so. Social attitudes, both cultural and interpersonal, clearly affect how health conditions and impairments impact people's lives, but the mechanisms underlying this impact are not at all well-known. We are even more ignorant of how macrolevel environmental changes in the form of laws and regulations, policies, and programs impact people's lives. While political activism may successfully alter our laws and policies, astonishingly, we lack the tools and indicators for identifying, let alone measuring, the impact of policy change on the lived experience of disability.

Universalism

Although it did not originate with the ICF, universalism is at the heart of the paradigm shift in our understanding of disability that the ICF offers. Conceptually, universalism stands in contrast to strains of cultural or social relativism that suggests that the disability experience is incommensurable between members of different cultures, or indeed between those with and those without disabilities. Politically, universalism rejects the claim that people with disabilities are a discreet and insular social minority group – a position that, as a civil rights movement, the disability rights movement successfully used to highlight inequities in the treatment of persons with disabilities, including marginalization and discrimination. Universalism does not downplay or ignore these inequities; indeed it heightens the scrutiny by emphasizing the need to socially 'mainstream' disability across policy rather than emphasis differences and 'special' provisions.

The sociological and political implications of treating disability as a universal human situation, and more practically of using ICF broadly as a policy tool for employment, education, and other social policies, have not been adequately explored. Although the planning and architectural program of 'universal design' is a dominant force in disability advocacy, the prospect of transforming universalism as an abstraction into concrete policy recommendations requires a solid empirical foundation that can only be provided by sound sociological research.

Human Rights and Justice

The ICF is, or at least was intended to be, an apolitical, even atheoretical, tool for collecting and analyzing comparable health and disability data. But there was also an implicit message in the ICF model that is politically significant: the administrative, political, and social world needs to be designed for all people, whatever their functioning characteristics. Political equality demands no less than the creation of social institutions that maximize opportunities for all, given the manifold ways that people differ. Differences that compromise equality – either because that limit the intrinsic functional capacity of a person, or because the physical and social environment creates unnecessary and unfair and burdens for the individual – need to be accommodated for the sake of equality of concern and respect.

This intuition, supported by the conceptual framework of ICF, is often operationalized in the language of rights – legal, civil and more generally, human rights. The United Nations' Convention on the Rights of Persons with Disabilities (UN, 2006) is the most recent statement of human rights in which the universalistic message of equal concern and respect for persons with disabilities has been enunciated. It is noteworthy that, although the Convention does not explicitly define disability, it characterizes it in language that is exactly parallel to the ICF: "Persons with disabilities include those who have long-term physical, mental, intellectual or sensory impairments which in interaction with various barriers may hinder their full and effective participation in society on an equal basis with others" (UN, 2006, Article 3). As with any lofty statement of human rights, the Convention will remain mere words unless given effect and implemented into concrete policies at the national level. Increasingly, human rights advocates have seen the need to marshal the resources of the social sciences in order to provide the robust, empirical evidence required to give effect to the aspirations of human rights treaties, such as the Convention. Indeed, this Convention explicitly requires states to "undertake to collect appropriate information, including statistical and research data, to enable them to formulate and implement policies to give effect to the present Convention" 2 7 (UN, 2006, Article 31). Social science in service of human rights, and aligned with the model of the ICF, is clearly anticipated by this Convention as a human right that persons with disabilities also enjoy.

Conclusions

The World Health Organizations ICF is a multifaceted document: It is a classificatory instrument designed to ensure comparable international information about health and disability to serve the informational needs across the health sciences, from public health and epidemiology to clinical care. The ICF offers the prospect of operationalizing the contentious notion of health in a way that maximizes its usefulness across professions, disciplines, and social sectors. The ICF is also a structural framework for health and disability measurement, the basis for assessment instruments, both specific and generic, and a common language that different members of multidisciplinary teams can used to serve the common interests of their patients. The ICF also offers the prospect of a universal framework for comprehensive disability policy development, including but extending far beyond the scope of health. Both conceptually and practically, the ICF opens the door to a vast range of applications and developments that are of great potential significance to the social and behavioral scientist.

Abstract

The history of funding in the social and behavioral sciences can best be described along different types of funding regimes. Starting with defining the term 'funding,' the article sets out to discuss those regimes and their emergence over the past two hundred years. It concludes with some remarks on recent discussions on the relationship of funding and research in the social and behavioral sciences, as well as some recent trends in their funding.

Introduction

To state the obvious right away: "Science costs money" (Stephan, 2012: p. 1). As in other fields, funding has been crucial for social and behavioral sciences from the very beginning. Surprisingly, however, so far its undeniable impact on the "social stratification of science" (Merton, 1988) has not induced comprehensive attempts to investigate the relationship of the disciplines toward funding. Reflection on the topic is restricted on case studies, which will be briefly discussed later.

Why are the social and behavioral sciences so timid when it comes to their endowment? One reason might be that there is a commonly shared uneasiness – to talk about funding might expose the disciplines as being compromised or manipulated. Any historical assessment of the social and behavioral sciences, however, cannot rely on the assumption "that there can be any pure form of social knowledge, uncontaminated by the situation in which it is created"; rather, it should be situated "in the context of the longer-term historical development of the relation between knowledge production and sociopolitical institutions" (Wagner, 2003: p. 546). The following sketch, as fragmented as it may be, is also an attempt to contribute to a history under such assumption.

Definition and Restrictions

A working definition of funding in the social and behavioral sciences encompasses the allocation of resources to allow trained personnel, for a time, conducting research on topics with relevance to social and behavioral sciences, and/or teaching those topics for training purposes. It would also include accompanying activities, such as advising and disseminating the results of the research, and fulfilling administrative requirements. Given this broad definition, it is tempting to sketch a simple, straight forward history of funding based on numbers: how many resources (valued in a standardized, aggregated currency) were allocated to the social and behavioral sciences? If it were possible to answer this question, it would provide a comprehensive overview about their relative worth, not only at a given time in a certain place, but also across regions and nations; in historical perspective, it would also allow to see allocation fluctuations over time. Of course, such a history cannot be written, at least not for now. First and foremost, the data are simply lacking. Current OECD data sets, for example, do not reach further back than to the early 1980s, since the Frascati Handbook, which is the internationally binding categorization system for science and technology statistics, included the social sciences only from 1976 (Godin, 2005a: p. 73).

Even for this rather short period, the figures displayed in Table 1 should be regarded with caution. First, the four countries were selected simply because they are the only ones where numbers are detailed along scientific fields, including the social sciences. Second, in the original table, every single data point contained a remark about specific methodological problems. Furthermore, it is not clear what 'all costs' really include, because the data collecting relies on national administrations and their standards are usually varying. "Statistics on science

Table 1 Expenditures in natural sciences and engineering and social sciences in four selected countries (in percent of total expenditures)

and innovation remain marked by significant methodological limitations" (Godin, 2005b: p. 15). That being said, thinking about the history of the social and behavioral sciences from the perspective of their funding might still yield some interesting, if not provocative insights.

At this point, it is helpful to distinguish also between different types of funding. The first type concerns direct, regular expenses, such as annual budgets for outfitting social science departments at universities, etc. The second type concerns direct, extraordinary funds, such as grants for social and behavioral research projects, or onetime investments to build up new infrastructure for teaching and research. The third type concerns indirect (mostly), regular expenses, including costs incurred through providing places at higher-education institutions for studying social sciences at different education levels. If the topic of funding has sparked interest at all among historians of social sciences, they have dealt with issues related to funding type number two. This is understandable, since this type of funding usually is the one most explicitly stated in historical records, as it is often the center point of concern in public discourses. For the remainder of this contribution, too, the main focus will be on the this type. For all its advantages that make it prone to historical analysis, however, it should be mentioned that, in relation to the two other types of funding, direct, extraordinary funding has to be considered rather small in size. If one were to discuss the public relevance of social and behavioral sciences in general, therefore, one would have to aim at an all-encompassing perspective.

Funding Regimes

From the point of their funding, the history of the social and behavioral sciences is to be written not only as one of remarkable growth in size. Over the past two hundred years, it also witnesses an increasing number of different procedures of allocating and accounting of funds. Those procedures can be described as funding regimes: As such, each of them implies a set of certain political purposes and addresses specific scientific practices, even though this may not be openly declared. Each regime's purpose is founded on ethical principles; the addressed scientific practices express specific epistemic expectations. Over time, more and more funding regimes evolve (with older ones usually being continued, albeit often significantly modified), offering more and more different sorts of funding and contributing to today's dense fabric of the social and behavioral sciences. Broadly, then, the history of funding can be described along different regimes of funding, each of which consisted of a unique mixture of ethical principles and the epistemic expectations.

Initially, there were basically two funding regimes: direct allocation of funds within state bureaucracies and philanthropic activities. Since the emergence of the social sciences is closely related to the rise of the modern state (Wittrock, 2000), the direct application of statistics became a crucial feature of the then still nascent state bureaucracy. Its purpose was to describe numerically the populace of a given territory, and it relied on the epistemic expectation to describe, rather than to analyze, the totality of the state's subjects (Desrosières, 1998). Census bureaus and statistical offices were usually directly connected to state apparatuses. In the beginning, at least, funding for this kind of activity was not yet on a regular basis.

Complementary, in all industrializing countries during the first half of the nineteenth century, individuals with a philanthropic background began addressing the need to respond to pressing social issues. Their curiosity was predominantly satisfied through social surveys, and it was clearly stimulated by political interest. For Friedrich Engels, "comprehending the present state of the English proletariat" was synonymous with his political sympathies for socialism (Engels, 1892). Others based their ambitions "to engineer the scientific management of the poor" on their religious beliefs, perceiving "disciplined ordering of the self and of the social world as the only possible bulwarks against the ever-surging sea of sin" (Yeo, 1991: p. 51). Soon enough, however, surveying also reached the policy arena: in England, Royal Commissions were established in order to investigate a range of issues, from the condition in coal mines to the traffic problems in London City. Here, surveying was no more the concern of affluent individuals but was intended to provide empirical evidence for public policy, particularly in its regulatory form.

When other forms of early funding emerged, they were based on a different set of core assumptions. As a sort of transitory vehicle, the efforts of the German Verein fur Socialpolitik contained the political interests of its members, but those were nonetheless intertwined with the social political program of the German Reich (Stremmel et al., 2006). As the social and behavioral sciences made their way into universities, they gained in autonomy (Shils, 1992); the relation between ethical principles underpinning the political purpose of funding changed, as did the epistemic expectations, but the strong connections were not lost. Nor did the older funding regimes lose traction. The statistical offices remained important centers of knowledge production and politically relevant, even though their practices were no longer considered the vanguards of research. With others, a division of labor was taking place. The philanthropic individual conducting research on his own (since its exponents were predominantly male) in the nineteenth century was replaced by the philanthropic foundation (based on the wealth of a philanthropic individual, nonetheless) that gave grants and fellowships to scholars (Bremner, 1988; Lingelbach, 2011). The financial means of the foundations were often enormous; their 'scientific philanthropy' relied on the idea that the "development of fair, objective, expert knowledge would enable all Americans [and eventually citizens of other nations, TK] voluntarily to coordinate and rationalize their actions" (Lagemann, 1992: p. 29).

As the last quote already indicates, the foundations were partly responsible for a major spatial shift of the center of social and behavioral sciences. From the 1920s on, that center was in Northern America, and no longer in Europe. In particular, the American foundations were critical in establishing what could be called 'big science' in the social and behavioral sciences through funding large projects (at least in comparison to other budgets in those disciplines), and in establishing new research institutions, within the US as outside (e.g., Hauptmann, 2012). Not surprisingly, thus, the processes of disciplining and professionalizing were strongly enforced by the foundations' funding activities (e.g., Capshew, 1999).

The US were also the first to see the advent of yet two other funding regimes that emerged during the first half of the twentieth century: independent funding agencies and research councils, and research commissioned by governmental institutions to (formally independent) research institutions. Before World War II, funding agencies and research councils relied mostly on privately raised money; only after the war, they were endowed by public funds. Despite the considerable differences that those funding agencies had in their national setting of science policy (Braun, 1997), they all were based on the idea that spending taxpayers' money through independent intermediary organizations would foster technological innovation and thus eventually stimulate economic growth.

The funding agencies established two important features of research in the social and behavioral sciences: The first feature was that research practices could be distinguished into basic and applied research. As they were supporting the former, the main purpose of funding agencies would become known as "policy for science" (Pulparampil, 1978: pp. 43–45). The second feature was that research should be done primarily in the form of projects. The social and behavioral sciences were often at the fringes of agencies' funding portfolio, since their main focus was on the natural sciences (although in the US and in the UK, research councils dedicated to the social and behavioral sciences also emerged). Still, agency funding probably had important effect on the developments particularly of psychological and economics research that successfully claimed to fulfill the epistemic expectation of scientific projects.

At the same time, the political agenda of governments was diversifying, and the 'applied' side of funding was taking off, too. Ministries and executive agencies commissioned research projects, either within their own administrative bodies, or to independent research institutions; sometimes they also supported entire institutions through block grants in order to facilitate long-term research on a certain subject. The most powerful funder became the U.S. Department of Defense, including its subbranches, such as the Air Force, which founded the RAND Corporation and its system analysis; other examples were intelligence analysis and counterinsurgency (Project Camelot). Yet another state-funded activity that became widespread in that period concerned academic exchange – not only a cheaper version than institution or project funding, but also differently framed under the key word of cultural diplomacy (Arndt, 2006). Commissioned research became a standard practice of governmental departments, and a major source of funding for social and behavioral sciences.

Obviously, the split between knowledge produced primarily for academia and knowledge produced primarily for political usage can be found in those two new funding regimes. Since then, no new funding regime has emerged sensu stricto. Rather, as the existing funding regimes were growing in number and size, they were increasingly subjugated under an all-encompassing metaregime of performance, with evaluation, assessment, and accounting as its basic means. In Great Britain, for example, the 'Research Assessment Exercise' was established with the hope to channel funding more effectively, essentially rewarding more productive researchers; in the US, a program called 'Star Metrics' now wants to verify how many jobs are created by grants of the National Science Foundation. In general, science policy has made a fundamental change in its focus, its principle now being 'science for policy.' Even basic research funding now must prove its impact, either in the academic world or through societal relevance.

A very popular recent categorization distinguishes research activities along two axes: whether or not the result is intended to be useful, and whether or not it aims at answering a fundamental scientific question (Stokes, 1997). From the four types of research that are constructed through this scheme, the one falling into 'Pasteur's Quadrant' is expected to be the most relevant, because it is supposedly advancing fundamental knowledge and at the same time expected to solve practical problems. Consequently, this kind of research is nowadays the most sought-for through funding schemes. For the social and behavioral sciences, this has on the one hand opened up new fields of activities – such as accompanying research, because it is supposed to help knowledge produced by research in the natural sciences to better relate to the public. On the other hand, It has increased doubts about the usefulness of research in some domains of social and behavioral sciences, as the recent debates in the US as well as in Europe bear witness (for Europe, see Mayer et al., 2013).

Controversies of Funding

The overview in the previous chapter treated the emergence of funding regimes as if they were unilaterally the same across the world. In some sense, there are indeed remarkable similarities across the globe, probably due to the internationalization of the academic world and the intrinsic power exerted by the US. That should not imply, of course, that funding regimes should be perceived as historical phenomena without links to political narratives and powers; quite the contrary. It would be interesting for more detailed historical analysis to find out the nuanced differences between similar funding modes in different regions of the world.

In historical terms, the different funding regimes (and their underlying ethical principles) have had impact on the shape of the social and behavioral sciences, at least in a very general sense. The regimes themselves came not into being without active shaping of social and behavioral scientists; one (in terms of funding involved) minor, but well-investigated case study that makes this very clear was the (failed) project of Max Weber's Presse Enquete (Weischenberg, 2012). The funding of 'big science' projects in the twentieth century would not have happened without crucial lobbying by representatives of economics, sociology, political science, psychology, and neither would have new institutions be founded. Similarly, the developments regarding the broader relationship of science and politics since the 1950s briefly outlined in the previous chapter are unthinkable without the theoretical concepts of economists and scholars in the field of science and technology studies, as they provided the basis for the narratives of science policy (Godin, 2009).

Often, the impact of funding is discussed within the social and behavioral sciences only on a polemical level. Two such controversies deserve to be looked at more closely. One concerns the (mostly historical) question whether research funding had any sort of impact on the shape of social and behavioral science disciplines; the other concerns the question

(focused primarily on the present) what the current forms of legitimation procedures of research funding decisions imply for research in those disciplines.

Has dedicated funding influenced the development of disciplines and fields in the social and behavioral sciences? Not surprisingly perhaps, this question has been posed in several disciplines in parallel and is always closely related to the issue of methodology. As is known today, there have been different phases of social research methods (Crothers and Platt, 2010). It seems natural to ask if those phases were connected to the emergence of new funding regimes. In sociology, the debate was sparked by the question whether the Rockefeller Foundation – for a long time the most affluent foundation active in funding social scientific research – had been preferred certain methodical approaches over others (Fisher, 1993). The allegation is difficult to get away with, although studies show that it is not vindicable (Platt, 1996). Similar allegations have made in political science, where the exclusion of political theory as one subfield of the discipline were supposedly the result of the work of foundations and political scientists alike (Hauptmann, 2006). Those historical debates, of course, have to be seen as one means in a broader context of redefining the disciplinary field in the present and in order to change them for the future (cf Engelmann, 2010). However, the larger issue at stake – reflecting the role of funding for social and behavioral research in face of historically shifting purposes and practices – remains underdeveloped.

Similarly, the current metaregime of performance begs the question how the shape of social and behavioral sciences is affected by it. While most scholars in the disciplines will not deny that meritocracy is an important feature in the academic world, there is often disgust displayed when the procedures established nowadays for legitimating the distribution of funding – projects and researchers are subject of many such procedures, from peer reviewing, evaluation, reporting, to accounting – are discussed. It is assumed that the research-funding apparatus established today has massive influence on language, style, scope, and behavior of researchers (Billig, 2013). Again, however, research is rather limited on that issue.

Changing Modes of Legitimacy

An important, though still underdeveloped question on the relation between funding and research activities in the social and behavioral sciences concerns the rhetoric of legitimacy of funding distribution over time. Lutz Raphael has recently suggested to divide the history of the social sciences into four configurations, in which not only the ideas and discourses and experts are taken into considerations, but also 'clients, institutions, and technologies' prevalent in each of those periods. According to Raphael, the period of 'social reform' lasted until 1910 and was superseded by the period of 'social engineering.' From the 1950s on, 'planned modernization' took place, which was replaced by 'the age of therapy,' from the 1980s on (Raphael, 2012: pp. 50–54). Broadly, those periods correspond with waves of new funding regimes as shown in the previous chapter. It is useful to look at those configurations also as a way to broadly understand the respectively accepted form of legitimacy for funding during each of those periods.

In the first configuration, when experts and clients were often close if not the same, and institutions as well as technologies not much advanced, funding required hardly any legitimation. The next period of social engineering, which saw the rise of the foundations, brought an important innovation. The large funds of the foundations required some sort of decision-making instrument. In the case of the Rockefeller Foundation, this was done by in-house and independent scholars who had gained the trust of the foundation's administrators (Fleck, 2011). Here, networks of trusted peers fulfilled the task of justifying the distribution of funds to scholars and researchers. When states entered the domain of research funding on large scale, the need to legitimate was further advanced. In the case of the agencies funding basic research, where the decision-making was basically left to (social) scientists, peer reviewing became the ultimate procedure of justification. In the case of commissioned research, the issue remained more in the dark, but it is obvious that it was left to a good part in the common interest between researchers and those commissioning the research. In the age of therapy, the metaregime of funding performance has given procedures such an important role that some of them, in particular decision-making, have become a topic of research themselves. Occasionally, a study in this field even makes it on the best seller list of social science literature (cf Lamont, 2009). Such studies bring great value to our understanding of legitimation procedures in the academia. What is missing, so far, is how those procedures influence the daily practice of scholars in the social and behavioral sciences.

Future Thinking

Stefania de Vito, University of Edinburgh, Edinburgh, UK; and Suor Orsola Benincasa University, Naples, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Thinking about the future can take numerous forms, varying from planning actions to foreseeing possible scenarios by means of knowledge and informed guesses, speculations and intuitions, or imagination and creativity. Different cognitive processes are needed for each of these different types of future thinking. The present article encompasses the relevant literature revolving around the issue of future thinking, that is, the cognitive ability, specifically of human, of envisaging one's own future. It aims at offering different interpretations about the relations between future thinking and a widespread range of other cognitive functions, like memory, executive functioning, and subjective time.

What actually occurs when we anticipate our personal future in thought is wonderfully expressed in the story of Apollo and Daphne. Apollo falls madly in love with Daphne. While running after the nymph, who desperately tries to flee from him, the god brags about being Jupiter's son and hence about his formidable power to clearly see the present, the past, and the future. However, Apollo, aspiring to Daphne's bed, hopes what he seeks and his hope becomes a misleading oracle. In fact, she begs her father's help to escape from the oracular god and obtains to be changed into a laurel tree (Ovid, "Metamorphoses," I book). More accurately than could any neuroscientific theory, the old myth shows what happens when people imagine their future. Even prophetic deities do regularly get it wrong. Nonetheless, we frequently act upon our fallacious predictions. Well aware that anticipations cannot be reliable, the Cumaean Sibyl paltered with a soldier, who consulted her about his fate in an upcoming battle, in a double sense: "*Ibis redibis non morieris in bello*," which sounds intentionally ambiguous unless one puts a comma before or after the word '*non*' (The sibylline statement might translate as follows: *You will go, will come back, will not die in the war*. In Latin, the word "*non*" could be yoked to "*redibis*" (i.e., You will go, will not come back, will die in the war), or with "*morieris*" (i.e., You will go, will come back, will not die in the war)) (de Vito and Della Sala, 2011). The present article aims at analyzing why our forecasts cannot be more precise than a sibylline prophecy without commas.

Conceptual Development and Definitions

Humans have the omnipresent faculty to think about their future. They do so by projecting themselves forward in time in richly detailed scenes and by imagining how different variations of an event will unfold. This ability is ubiquitous, given that, far from being idle in the absence of external task direction, our brain is spontaneously and constantly (also in the default – passive – cognitive state) engaged in devising simulations that might approximate real future events (Ingvar, 1979; Bar, 2007; Buckner and Carroll, 2007; Buckner et al., 2008). Thus, people might either deliberately cast themselves into hypothetical futures or unexpectedly think of their future during the unoccupied moments of daily life. According to Cicero, Cato used to say that "never is a man more active than when he does nothing, never is he less alone than when he is by himself."

This complex process reflects a composite of cognitive functions. An ongoing research aims at characterizing these components and assessing their specific roles. The gist of the debate mainly revolves around episodic/non-episodic contributions to future thinking.

Initially, researchers have emphasized the importance of the episodic contribution, considering episodic memory as a fundamental part of future thinking, since it provides the 'raw material' (Suddendorf, 2010: p. 100) to envisage situations likely to occur in the future.

The preferential focus on episodic memory, rather than on other memory systems, such as semantic memory, seems to stem from the unique relationship that episodic memory bears with time, a relationship of which semantic memory system is devoid of (Tulving, 2002). Episodic memory, indeed, differs from semantic memory in the diverse typologies and sources of to-be-remembered information. That is, individual experiences in the former case and general knowledge of the world in the latter (Tulving, 1972). Thus, only episodic memory has the special connection with time, which enables "people to consciously re-experience past experiences" (Tulving, 2002: p. 6).

The relations between the past and the future have been variously identified as "continuation of a repeating past" and "projection of past trends" (Haith, 1997): people are inclined to predict a reoccurrence in the future of what happened in the past (respectively, *verbatim* or through a detail recombination). The second type of relation is close to Tolman's "theory of expectancy" that illustrated how rats might flexibly recombine prior experiences to deal with *ex novo* situations. The use of memory may be instrumental in the development of adaptive responses that extend beyond the stereotyped recurrence of reinforced sequences (Tolman et al., 1946). However, there is another possibility that Haith (1997) labeled "imagination and invention," which contemplates the imagination of novel episodes that have never happened, like a hypothetical trip on Mars. In this case, "episodic memory (together with other memory systems) may hence provide the vocabulary for episodic foresight. Humans can recursively combine and recombine basic elements into novel scenarios and evaluate these in terms of their likelihood, desirability and so forth" (Suddendorf, 2010: p. 101).

Subsequent considerations concerning the ability of foreseeing by reshuffling different snippets to shape novel arrangements have led to the hypothesis that also processes

unrelated to episodic memory play a crucial role when imagining the future. Therefore, in the attempt of gaining greater control over the simulation of scenes, a more recent branch of research has been addressing the non-episodic contributions to future thinking (e.g., Rosenbaum et al., 2009; Gaesser et al., 2011; de Vito et al., 2012). Instead of considering episodic memory as a "vocabulary" of elements on which to draw to foresee, it has been argued that episodic memory and future thinking share the same neurocognitive resources. They might draw on a widespread range of specific abilities, like a particular type of consciousness (autonoetic consciousness; Tulving, 1985), the ability of binding details, executive functions, self-projection, and related capacities, like conceiving others' viewpoint (theory of mind) (Buckner and Carroll, 2007). That is, a number of cognitive functions other than episodic memory, unconnected with both recent and remote autobiographical episodes, might play an integral role when constructing scenes.

Szpunar (2010) noticed that even the heterogeneous nomenclature adopted to identify forethought depends on whether or not it was meant to highlight the tight linkage with episodic memory. Atance and O'Neill (2001) have built their definition of "episodic future thinking" upon Tulving's most recent conceptualization of episodic memory. Indeed, the two researchers formulated a specular distinction between semantic and episodic future thinking, which mirrors Tulving's categorization for past memories. Whereas semantic future thinking concerns the projection into the future of a general knowledge of the world and, consequently, of reasonably good scripts, episodic future thinking "refers to an ability to project the self forward in time to pre-experience an event" (p. 537). In-line with Tulving's theory, they maintained that the episodic memory system underlies the capacity to cast personal events into the future. A key account for this linkage has been provided by Suddendorf and Corballis (1997), who referred to the ability to mentally travel in time as "a prime mover in human cognitive evolution" (p. 165). For our survival, episodic memory informs us about potential futures (Suddendorf, 2010). The "constructive simulation hypothesis" arises from this evolutionary perspective and states that the mechanism lying behind the episodic memory evolved as constructive rather than reproductive to allow individual simulations. People can collect elements from different memories and combine them in an unpredicted manner to shape unique scenarios (Schacter and Addis, 2007). In order to plan the future, we need a system of representations rather than mere recordings of events. Thus, according to this view, memories are considered as "building blocks of predictions" (Bar, 2007: p. 280). That is, the linked stored elements activate associations that are relevant in a specific situation. Predictions are generated by these associations, which is why they so often go awry.

On the contrary, when researchers did not intend to emphasize the connection with episodic memory, referred to the capacity of formulating prospects as "projection" (Okuda et al., 2003) or "prospection" (Gilbert, 2006).

Although episodic future thinking is a unique mental faculty, originally, the concept has been extensively discussed in relation to episodic memory. To this discussion, we will turn next.

Episodic Contribution to Future Thought

It has long been posited that an intimate relation underpins episodic past and future thoughts. Immanuel Kant had this insight in 1798: "Recalling the past (remembering) occurs only with the intention of making it possible to foresee the future; we look about us from the standpoint of the present in order to determine something, or to be prepared for something. Empirical foreseeing is the anticipation of similar cases (exspectatio casuum similium) and requires no knowledge of causes and effects, but only the remembering of observed events, as they usually follow upon each other. Repeated experiences help to develop skill in empirical anticipation" (1996: p. 77). Past memories are thought to play an essential role in driving future simulations to such a point that when no parallel in the past is found to what is occurring, people get lost: "as the past has ceased to throw its light upon the future, the mind of man wanders in obscurity" (de Tocqueville, 1863: p. 408). The recurrent observation that "we have no grasp of the future without an equal and corresponding outlook over the past" (Bergson, 1913: pp. 69–70) led William Faulkner to state that "the past is never dead, it is not even past" (1951, Act 1, sc. 3), and René Char to complain about the lack of a "testament" that could show us how to use our "inheritance." Consistent with these precocious considerations, functional magnetic resonance imaging (fMRI) studies have shown that remembering and imagining the future engage a common core network, encompassing specifically the medial prefrontal cortex, posterior regions in the medial and lateral parietal cortex, the lateral temporal cortex, and the medial temporal lobe, including the hippocampus (Okuda et al., 2003; Addis et al., 2007; Szpunar et al., 2007). Future episodes simulation has been shown to activate the hippocampus, a region that is traditionally considered to play a fundamental role in memory encoding. In particular, preferential right hippocampal engagement has been observed when imagining the future relative to remembering past. There has been an increasing interest in interpreting the specific contribution that hippocampus makes to prospects and, consequently, in understanding the relation between remembering and future thinking. Critical lines of inquiry are to determine whether or not the hippocampus plays a crucial role in future thought, and which processes rely on the hippocampal activation.

Some amnesic patients are reported to be prisoners of a permanent present (O.S., Lidz, 1942; G.A., Dalla Barba et al., 1997; D.B., Klein et al., 2002). Five patients with bilateral hippocampal damage, encouraged by Hassabis et al. (2007) to generate "as many sensory and introspective details as they could" about a fictitious event, depicted very poor scenarios lacking in spatial coherence. Likewise, a group of patients suffering from mild Alzheimer's disease (Addis et al., 2009), a group of patients with amnestic mild cognitive impairment (Gamboz et al., 2010), and patients with medial temporal lobe damage (Race et al., 2011) uttered fewer details in a future thinking task than their matched controls. When asked about personal plans in the next future, most of these patients answered in the same way. At the question, "What are you going to do tomorrow?", the famous amnesic patient H.M. replied, "Whatever is beneficial" (Corkin, 2002); K.C., who suffered from a dense amnesia following frontal and medial lobes damage,

smiled faintly, then answered, "I don't know," and, when required to provide further explanations, said, "It's like swimming in the middle of a lake. There's nothing there to hold up or do anything with" (Tulving, 1985: p. 4); M.C., with bilateral hippocampal damage, replied, "I don't see past, today and tomorrow, and can't picture myself in anything beyond the immediate present" (Andelman et al., 2010: p. 432). Nonetheless, the role played by episodic memory in the construction of future prospects is still controversial.

The Debated Role of Episodic Contribution in Foresight

There is a substantial amount of similarities between remembering episodic memories and imagining future events. However, these similarities are to be treated with caution. Recently, it has been suggested that episodic memory may not be a *condicio sine qua non* in simulations of future scenarios. Such an intuition has also been corroborated by several criticisms to the studies mentioned above and consequent research. Some of the studies mentioned earlier do not detail the lesion location of the amnesiacs (O.S. and D.B.). In other cases (K.C. and Hassabis and colleagues' patients), the information provided indicates an extensive damage, including impairments encroaching upon areas beyond the hippocampus, as Squire et al. (2011) argued. Furthermore, a crucial caveat to the hypothesis that the two time-related functions might be closely interconnected is that a number of amnesiacs show preserved ability to perform constructive tasks. Spared future thinking capacities in a context of amnesia and hippocampal damage have been observed in five amnesic patients whose performance fell within, or even above, the control range (Squire et al., 2010), in the single case of Jon, with developmental amnesia (Maguire et al., 2010); in a group of 21 children with a bilateral hippocampal damage (Cooper et al., 2011); and in P2, one of the patients examined by Hassabis and colleagues (2007) (for a review, see Addis and Schacter, 2012). These observations downsize the importance of episodic memory and hippocampus in future imaging. The relationship between remembering the past and imagining the future appears to be more subtle than it has been postulated in various studies. Information about specific events that have already occurred might not be necessarily needed. A loss or a reduction of episodic memory might be compensated with an increased reliance on semantic information when remembering (Levine et al., 2002), when imagining (Gamboz et al., 2010), and even when more basically describing pictures (Gaesser et al., 2011). People can easily generalize and extrapolate information from their general knowledge, adding arbitrary particularities. "Without the ability to extrapolate from generalities, the amount of particularities the brain would have to store would be subject to a combinatorial explosion. For every prediction of a future event, the memory of a corresponding past event would be needed. Conversely, what one can predict about the future will be limited by one's episodic memory" (Hegdè, 2007: p. 324). If it was strictly true that episodic memory helps to pre-experience future episodes, this would imply the possibility of foreseeing only those events that we have episodic memory of. Furthermore, if it was true that one could predict his future only on the basis of his past, and to the extent that events never replicate themselves precisely, one could never apply any past memory to a future simulation (Hegdè, 2007). Therefore, without unnecessary limitations, it can be argued that different types of memory might cooperate with each other and with other cognitive domains to aid forecasting.

When participants attempt to build personal futures in response to verbal cues, they rely upon disparate elements from a number of sources, which cannot be solely identified in episodic memory. D'Argembeau and Mathy (2011) found that when attempting to think about a possible future episode, people most frequently activate general knowledge. There is also much evidence that when adults are required to complete sentences about their personal future (e.g., "Next year I… ."), they frequently report future thoughts concerning extended future life periods or personal semantic information (Anderson and Dewhurst, 2009). And, in fact, a considerable number of future simulations consist of abstract representations rather than specific events (D'Argembeau et al., 2011). These findings raise the possibility that access to episodic details might be not necessary. In the absence of episodic memories, one might adopt compensation strategies and rely on semantic information. Indeed, latest studies using fMRI have provided no evidence of a hippocampal involvement in subjective time travel. Nyberg et al. (2010) required well-trained participants to imagine walking in a familiar environment in the past, present, and future. Thus, they were not asked to create an episode content but solely to self-project in a standard situation recurring in different temporal frames. The task, which held constant the informational content, did not recruit the hippocampal region. The authors interpreted their findings, suggesting a closer relation between the hippocampus and the 'message,' rather than between the hippocampus and the "conscious temporality of the experience" (p. 22357). Likewise, Squire et al. (2010) reported on future thinking performances in five patients with a well-characterized bilateral hippocampal lesion and one patient with extensive medial temporal damage, presenting with a subsequent, respectively, moderate and marked impairment in recent personal memories. The intact ability of these patients in future thinking sharply contrasted with their striking impairment in recalling recent past episodes. Consequently, the authors suggested that a selective hippocampal damage, which spares the rest of the core network proposed, is not sufficient to affect future imaging. Maguire and Hassabis (2011) assumed that the patients could have supplied reports more semantic in nature, prompted by the single word cue, likely to cause a semantic bias. However, Squire et al. (2011) noticed that also one of the patients (P1) described by Hassabis et al. (2007), albeit the marked amnesia, was successful at constructing scenes. And in that case, the scenes construction was elicited by full sentence descriptors. This demonstrates that amnesia per se does not necessarily affect the ability of simulating scenes.

Episodic retrieval might not be sufficient for future events to be shaped. For instance, Romero and Moscovitch (2012) suggested that the re-encoding of retrieved snippets into novel events is another aspect of event construction that might change with age and medio-temporal lobe dysfunction. In their study, indeed, the relative coherence of imagined events decreased in older adults when the number of given items to be

integrated was higher. Therefore, in addition to the access to episodic details, there are at least three more functions that are essential in allowing future event simulations: the production of specific details not necessarily episodic in nature, the actual construction of the episode itself, and the awareness of the plausibility of the imagined event.

First, obviously, the ability of future thinking is related to the capacity to produce specific personal details, mediated by executive control. These details might also be produced in conditions that do not require an involvement of episodic memory (when, for instance, participants are simply required to describe an environment or a picture).

For what concerns the construction of the episode itself, it should be considered that as long as we have a jumble of snippets, we have to reshuffle them in novel patterns. This step is even more complex in future thinking than in episodic memory. Whereas past episodes require a search for an exclusive arrangement of information, future thinking is open-ended. The number of potential scenarios that one might envisage is infinite. Future events might be shaped with any arrangement of an unlimited array of information (Suddendorf and Corballis, 2007; Anderson et al., 2012).

At this point, during and after the construction of the event, we have to evaluate whether the event is actually likely to happen in the future, considering our background, our personal history, and our past and present situations. Therefore, the feasibility of our scenarios has to be constantly monitored.

Non-Episodic Contribution to Future Thinking

Our mind does not work like a video camera and we do not have at our disposal full-fledged scenes to be performed as in a movie ("The past, like the future, can only be imagined"; De Hériz, 2006: p. 21). Episodes are constructed by drawing from different snippets and by reshuffling them to form infinite and elaborated simulations of possible upcoming episodes. The construction of such simulations implies an interaction of different functions that play crucial roles in the production and the flexible combination and integration of the amount of the available details into a coherent whole. The generation of detail-rich descriptions requires reconstructive mechanisms for the binding of information, which are, in turn, mediated by executive control. Deficits or decline of these mechanisms might hamper the generation of details and, consequently, account for impairments in a wide range of conditions. At odds with what Levine et al. (2002) and Addis et al. (2008) maintained, the reduction in specificity observed in elderly people does not entirely reflect an impairment of the constructive episodic memory system underling both past and future thoughts. And indeed, such reduction also extends to tasks that do not require an access to episodic details. Gaesser et al., (2011) documented an age-related decline in reporting details also during a condition of picture description task, which does not necessitate episodic memory. These findings uncovered a non-episodic source of age differences in past and future thinking tasks, a source unrelated to memory itself. Such observations were instrumental in the development of other studies designed to explore the possible causal link between executive functioning and future prospects, in the attempt of gaining greater control over the simulation of scenes. This new branch of research takes into account that the extensive damages exhibited by the amnesic patients described in the previous paragraph also include areas that play a crucial role in executive functions (e.g., see Samarasekera et al., 2007). Rosenbaum et al., (2009), for instance, a more general construction deficit as a plausible and alternative root of K.C.'s impairment in future simulations. Aiming at testing this possibility, K.C. was required to produce fictional episodes and to retrieve or identify elements of semantic narratives (famous fairy tales and bible stories). Also, in these conditions, the patient's scores fell well below the control range. These results speak against the episodic constructive simulation hypothesis. If future simulations must rely on the reformulation of past personal memories, then K.C. should have presented with a normal recollection of semantic narratives, albeit his severely impaired autobiographical episodic memory. However, this was not the case. Indeed, he failed to construct detailed and integrate narratives even when the necessary information was available. Similar results have been obtained by Addis et al. (2010), who documented an age-related reduction in specificity also under a recombination paradigm, simply requiring healthy older adults to reformulate various elements into a cohesive episode. In-line with these evidences, Addis et al. (2008) noticed a close linkage between tasks involving executive performances and tasks requiring episodic elements generation. In their study, the amount of episodic details that were provided in the past and future reports correlated with the Backward Digit Span task, which measures the executive control and engages the dorsolateral prefrontal cortex (Hoshi et al., 2000). Accordingly, a number of neuroimaging studies have shown a greater frontopolar activation, including BA 10, during future thoughts than during past recollections (Okuda et al., 2003; Addis et al., 2007; Summerfield et al., 2010). Interestingly, the greater was the activation of BA 10, the larger was the amount of elements provided in future constructions (Addis et al., 2008). In another fMRI study, Summerfield et al. (2010) showed which components of the core network (Schacter et al., 2007) are variably engaged and disengaged during the various steps of a scene construction task. The participants were instructed to combine the single-scene elements they were provided within a cohesive scenario. The details were presented one at a time with no context. The fMRI documented a significant activation of the hippocampus and the dorsolateral prefrontal cortex during the presentation of the first element. However, the introduction of the second element did not recruit the hippocampus but required an increasing activation of the dorsolateral prefrontal cortex, perhaps to maintain two elements in working memory. The addition of the third element upregulated several regions (i.e., the medial parietal cortex), downregulated in both the previous phases, and increased the activation of the hippocampus. Thus, the hippocampus might not be invariably required in a construction scene process. On the contrary, frontally based executive functions are likely to be an integral part of the episodic elements reformulation mechanism.

Another frontally based function, of which future thinking is considered a 'prototypical example' (Buckner and Carroll,

2007: p. 50), is the self-projection. Self-projection is a striking feature of our cognitive system that allows us to shift personal perspectives from the immediate environment to alternative situations. The brain network engaged in self-projection embraces frontal lobes and medial temporal–parietal lobes, which are also upregulated in envisaging the future and episodic remembering, theory of mind, and navigation. Buckner and Carroll (2007) considered these abilities as single components of a broader number of functions. They maintained that the adaptive value of episodic memory lies in its contribution to conceiving mental models of what might happen in the future or other perspectives on the surrounding environment, such as what others are thinking. However, some answers provided by K.C. stand in stark contrast with this hypothesis. When asked, in more than one occasion, to describe what he felt when trying to imagine a future scenario, K.C., as previously mentioned, claimed, "It's like being in a room with nothing there and having a guy tell you go to find a chair, and there's nothing there" (Tulving, 1985: p. 4). This observation uncovered his ability to project himself in different situations. Although he did not provide much detail, he was able to shift his perspective from the immediate environment to alternative presents. And indeed, many years later, Rosenbaum et al. (2007) documented that K.C. preserved his ability to infer other people's thoughts, presenting no difficulties in tasks assessing theory of mind. Therefore, the authors argued that theory of mind's abilities, which are strictly related to self-projection, can be uncoupled by severe impairment of episodic memory and autonoetic consciousness. On the contrary, some researchers consider the concept of autonoetic (derived from the ancient Greek words αὐτός, which means 'own self,' and νοέω, which means 'I think') consciousness as closely related to the capacity of self-projecting into the future (Tulving, 1985; Dalla Barba et al., 1997). When a person remembers an event from his own past, this kind of consciousness confers the awareness that the event is actually a veridical part of his personal past experience (Tulving, 1985). The awareness of subjective time, or temporal consciousness, allows the cognizance of a unique sense of time extending from the past to the future, passing through the present moment (Wheeler et al., 1997). In fact, temporal consciousness usually interacts with less stable, and thus more vulnerable, modifications in the long-term storage system. This work allows quick and steady updates in present orientation and future planning. When temporal awareness is in the condition to make use solely of the more stable modifications of the long-term storage system, the result is that a patient might remember "another" past and plan "another" future, mistakenly involving his habits and personal semantic information in a personal temporal workspace (as in the case of G.A., described by Dalla Barba et al., 1997).

Conclusions

Overall, recent literature seems to suggest that general knowledge and frontally based functions, other than episodic memory, are fundamental when thinking about future. Future thinking is a costly process, which, far from being an encapsulated cognitive function, impinges upon a constellation of constituent abilities. The mental creation of future experiences requires the activation of much of cortical mass and it is likely to be disrupted at different stages, and potentially by "any kind of cortical brain damage" (Berryhill et al., 2010: p. 1391). The matter is intriguing, given that we are all prone to act into the present according to our predictions. Our behavior is determined by personal past experiences and by designs formulating the future. As in Kafka's parable, the individual, "He," gives battle in the present to two antagonists: his past and his future. "The first supports him in his fight with the second, for he wants to push him forward, and in the same way the second supports him in his fight with the first, since he drives him back" (1972: pp. 811–812). Past events never replicate themselves in the same manner. Nonetheless, they undeniably affect our future-oriented thoughts and, consequently, our present. This is the reason why it has been suggested that the best way to predict the future is to forget what we know and give free range to our imagination. "All the rest does not exist, yet. To invent it. That would be wonderful" (Baricco, 1993: p. 143, own translation). And, indeed, Tiresias, legendary prophet of Thebes, was blind. Metaphorically, his prophecies ignored the surrounding environment. Perhaps instead, the best way of thinking about the future is to use our imagination to re-create the past. In this way, we will avoid to be driven back by our past experiences and will rise up, as Kafka wished, to the position of umpire over the two antagonists in their fight with each other.

Abstract

In this article we discuss future time perspective (FTP) and future orientation (FO) as two cognitive–motivational conceptualizations of future thinking. We first delineate each conceptualization and conclude by highlighting some of its commonalities and differences. We then summarize research on the motivational antecedents and consequences of FTP and FO. Finally we relate our research to three issues: Why is it that not all future thinking prompt behavior? Does culture (as well as other aspects of the social milieu) matter? How can our research findings be implemented to improve individuals' prospects?

Introduction

People live of course in the present, in the here and now, but they also live to a certain degree with their past and they can foresee a more or less distant future. The personal past, present, and future are psychologically integrated in the psychological life space (Lewin, 1942) so that the psychological present encompasses all three time periods: the experienced present, remembered past, and anticipated future. Depending on which of the three time periods is the most dominant part of their present life space, people are either past-, present-, or future-oriented (Zimbardo and Boyd, 1999). While each orientation may have distinct effects on present behavior, our aim here is to focus on the future and describe its motivational properties.

Of the multiple conceptualizations psychologists have been using to describe future thinking (Seginer, 2009), in this article we address mainly two: the future time perspective (FTP) and future orientation (FO). The article consists of three parts. In the first we delineate each conceptualization and conclude by highlighting some of its commonalities and differences. In the second we summarize research carried out mainly in the last decade on the motivational consequences of FTP and FO. In the final part we summarize our research by relating to three issues: Why is it that not all future thinking prompt behavior? That is, what conditions enhance or decrease future thinking–behavior relations? Does culture (as well as other aspects of the social milieu) matter? How can our research findings be implemented to improve individuals' prospects?

Two Conceptualizations: FTP and FO

Future Time Perspective

FTP is the degree to which, and the way in which, the future is anticipated and integrated in the psychological present of an individual (Lewin, 1942). Two important characteristics of the individual FTP are its extension and its content: How far into the chronological future reaches one's psychological future and what does one anticipate in the future? Does it consist mostly of positive or negative events, hopes, or fears? Which life domains are predominantly anticipated: education, work, family life, and leisure (Seginer, 2009)? As we will document, both aspects – extension and content – are motivationally relevant.

For two reasons, we conceptualize FTP as a cognitive–motivational variable: It results from goal setting and has motivational consequences (Lens, 1986).

FTP Results from Goal Setting

Formulating distant motivational goals and developing long-range behavioral projects to achieve those goals, create a long or extended FTP. People with a rather short FTP set most of their goals in the near future and do not take into account what will come later. People with a longer or deeper FTP formulate relatively more long-term goals and their present temporal life space extends into the very distant future. They have no problem at all to reckon, already now, with or to be motivated by events or action outcomes in the rather distant future (Lens, 1986; Seginer, 2009).

People have a rather long FTP not only when they set goals for themselves in the rather distant future but also when they take into account in the present personally relevant events that may happen to them in the distant future, even in the afterlife. Boyd and Zimbardo (2005) developed a scale measuring the transcendental FTP with items that suppose the belief in life after death (e.g., My body is just a temporary home for the real me; Humans possess a soul). For a review of other techniques used to measure FTP, see Nuttin et al. (1979).

Other aspects of FTP than its extension are the degree of realism, density (i.e., how many goals or events are foreseen), structure (e.g., means-end relations) (Lens, 1986); and connectedness with the present (Husman and Shell, 2008) as endogenous and exogenous relationships between present and future goals (Husman and Lens, 1999). Especially the content of FTP is getting more and more research attention. Nuttin and Lens (1985) developed a coding system identifying the content of future goals (e.g., self-realization, knowledge, affiliation, power, achievement, etc.).

Based on the self-determination theory (SDT, Deci and Ryan, 2002) de Bilde et al. (2011) distinguished intrinsic and extrinsic future goals. Peetsma and Van der Veer (2013) and Seginer (2009) analyzed people's FTP – mostly adolescents and emerging adults – in different life domains such as

[†] Deceased.

education, work, leisure, and family life. People do indeed not anticipate an empty future, they anticipate positive and negative events, they formulate hopes and fears for the future, they pursue positive (i.e., things they want to achieve) and negative (i.e., things they want to avoid) future goals. Seginer (2009) described this as a thematic approach of FTP and distinguishes it from an athematic approach. In the athematic approach of FTP, one only considers to what extent people are future-oriented, how far into the future people anticipate, to what extent they link their present and future life periods, and whether they view the future as mainly positive or negative without considering any contents.

FTP became the object of predominantly correlational studies, relating individual differences in the length or extension of FTP (and its content) with other personal characteristics such as intelligence, age, gender, socioeconomic status, ethnicity, well-being, self-esteem, achievement motivation, delinquency, substance (ab)use, and health behavior (see Seginer, 2009). Given the correlational nature of these studies and absence of longitudinal approaches, the findings did not really allow inferring causal antecedents of differences in FTP. There was, and still is, a lack of research on how to develop a longer FTP or how to help elderly people to stay future-oriented, rather than turning too early in life to a less motivating past- or present orientation.

In summary, the concept of FTP as an individual psychological construct is a rather simple one: How far into the future do people project their goals and what type of goals, aspirations, and fears do they have? How far into the future do they anticipate personally relevant events and what is the content of those events, which life domain do they represent? Do individuals and social groups differ in the content of relevant events?

Starting from this unidimensional cognitive–motivational conceptualization of FTP and other similar conceptualizations Seginer (2005, 2009) developed a multidimensional conceptualizations of FTP – or FO according to their terminology – each consisting of three components. Here we describe the conceptualization initially developed by Seginer et al. (1991) and further elaborated by Seginer (2009; Seginer et al., 2004).

A Three-Component Model of FO

Although here we focus on the three-component model, we start its presentation by briefly describing its evolvement out of the unidimensional approach.

The Unidimensional Approach

A basic premise of the FO conceptualization has been that FO is not about predicting the future but about the subjective images individuals hold about it. These images are thematic (Nuttin and Lens, 1985), expressed in terms of the *hopes* individuals have about the future and the *fears* they would rather avoid (Trommsdorff, 1983), and can be subsumed under life domains such as education, work, and family. Work carried out in Israel showed that adolescents growing up in such diverse sociocultural milieus as Jewish urban and kibbutz, Muslim, and Druze rural communities described the future in terms of six common life domains: education, work and career, marriage and family, self-concerns, others, and the collective. Given the normative life course of Jewish adolescents and Druze boys, their FO includes also military service.

While the domains were similar, endorsement has been culture specific. Thus, Muslim and Druze girls construct an FO that has high-density (i.e., relative representation) higher education. Moreover, data collected for over 20 years show Muslim and Druze girls list more hopes and fears about higher education than do Muslim and Druze boys and Jewish girls and boys (Seginer, 2009).

The advantages of the unidimensional approach notwithstanding, its narrow conceptualization and methodological limitations led to the construction of the three-component model. This model draws on the FO unidimensional conceptualization in two ways. First, it takes the cognitive representation as its starting point, and asks two questions: What prompts the cognitive representation of the future and what are its outcomes. Second, given that time images are not void of content, the model applies to each of several future life domains, thus preserving the thematic approach to FO.

Expanding the Model

Drawing on a basic premise that cognitive representation is prompted by motivational forces and often results in behavior, the expanded model consists of motivational, cognitive representation, and behavioral components. Together they form a multiple-step model in which the motivational component affects the cognitive and the behavioral components, and the cognitive component affects the behavioral component (Seginer, 2009). The components are theoretical and indicated by empirical variables as next described.

The Motivational Component

Drawing on motivation theory and earlier conceptualizations of FTP (Nuttin and Lens, 1985) and FO (Trommsdorff, 1983), three empirical variables indicate this component: the *value* of the prospective life domain; *expectance* defined as the subjective probability that hopes and plans will be materialized, and its affective tone. The third is a sense of *internal control*: the person's responsibility for the materialization of future hopes and plans.

The Cognitive Representation Component

This component relates to the extent to which individuals think about the future, in terms of hopes and fears about each future life domain.

The Behavioral Component

Its conceptualization draws on the work of Lewin and Erikson. *Exploration* relates to seeking information and advice regarding future options and testing how well they fit personal abilities and values, social expectations, and environmental circumstances. Commitment consists of the decision to pursue one option and results in "a sense of knowing where one is going" (Erikson, 1968: p. 165). Both add to the instrumentality of FO and prompt the achievement of future hopes, goals, and plans.

The Importance of Content: Domain Specificity

The three-component model applies to each of several future life domains included in individuals' future life space. Its viability is supported by empirical findings indicating the domain-specific effect of FO on present behavior (Seginer, 2009).

Summary: FTP and FO Commonalities and Differences

A basic premise common to the FTP and FO is that time perspective is content-based. Thus, both approaches are thematic. Moreover, while both understand the motivational qualities of future thinking, they also emphasize conditions enhancing and reducing motivation for present behavior (see Summary and Conclusion section). The two approaches differ on three main issues: only FTP conceptualization emphasizes extension, the FO approach is more concerned with various life domains and cultural context. Finally, in the FTP theoretical framework, goals precede FTP whereas in the FO conceptualization, goal setting follows FO.

The Motivational Consequences of FTP and FO

Motivational Consequences of FTP: Extension and Content Matter

Extension of FTP Affects the Quantity of Motivation

Estimating the present motivational effects of future goals by using the 'expectancy × value' or the 'expectancy × instrumentality × value' theories of motivation (Eccles and Wigfield, 2002) has been proven useful. Extension of FTP is positively related to motivation: Students with a longer FTP are in general more motivated. How comes? Extension of FTP is negatively related to the psychological distance toward moments in the near or distant future. Differences in extension will probably not affect the psychological distance to moments in the very near future (e.g., tomorrow, next week) or the very distant future (e.g., 50 years from now for an adolescent). But, for example, 1 or 5 years from now into the future is psychologically much closer for people with a long FTP than for those with a short FTP. This has two motivationally important implications: anticipated value of the future goal and perceived instrumentality of present actions. In general, the anticipated rewarding value of a given goal decreases the more delayed it is. But this decrease is less steep for people with a longer FTP. This can explain why students with a short FTP may choose to become a nurse after 3 years of study rather than a physician after 7 years, or discount the possible unhealthy and even dangerous future consequences of present risky sexual behavior, smoking, drinking, and using drugs (Keough et al., 1999; Apostolidis et al., 2006). Second, the longer the FTP, the easier it is to see the instrumental or utility value (Eccles and Wigfield, 2002) of present actions. For example, students with a longer FTP have not only educational goals for the near future but also educational and vocational goals in the more distant future. Their present study activities are more instrumental, have a higher utility value than for students with a short FTP. As predicted, perceived instrumentality is positively related to motivation in education (Andriessen et al., 2006; Husman and Shell, 2008; Mikkonen et al., 2013). An important limitation of most of these studies is that they are correlational and cross-sectional so that there is no room for causal interpretations.

Content of FTP Affects the Quality of Motivation

The motivation to pursue future goals is by definition extrinsic motivation and especially in educational psychology extrinsic motivation was considered to be of lower quality than intrinsic motivation. More recent empirical research based on the SDT (Deci and Ryan, 2002) shows that not all types of extrinsic motivation are of low quality motivation. The intrinsic–extrinsic distinction is replaced by the more valid distinction between autonomous motivation and controlled motivation. An autonomous motivation is 'high-quality motivation'. When behavior is externally regulated (e.g., by rewards, punishments, supervision, etc.) or regulated by introjected motives (e.g., avoid shame and guilt feelings) its motivation is controlled and thus a nonoptimal type of motivation. When it is intrinsically motivated its motivation is autonomous, volitional. However, extrinsically motivated behavior regulated by future goals that are personally important (e.g., to become a psychologist; identified regulation) or perceived as totally congruent with one's true self (e.g., to become a physician with doctors without borders; integrated regulation) is also autonomously motivated.

Whether future goals create controlled or autonomous motivation depends on their content. SDT makes a distinction between intrinsic and extrinsic goals (Deci and Ryan, 2002). Intrinsic future goals create autonomous motivation and extrinsic future goals create controlled motivation. Examples of intrinsic goals are self-development, physical fitness, competence, community contribution, affiliation, altruism, etc. Examples of extrinsic goals are financial success, power, status, physical attractiveness, outperforming others, admiration, etc.

There is ample empirical evidence from correlational but especially from experimental research in real life conditions that experimentally inducing future intrinsic goals has more adaptive outcomes than inducing extrinsic goals (for a review, see Lens et al., 2012).

The SDT (Deci and Ryan, 2002) predicts that pursuing intrinsic goals is always, everywhere, and for everybody better than pursuing extrinsic goals. This difference is explained by the fact that intrinsic goals satisfy and extrinsic goals frustrate the three innate basic psychological human needs proposed by the SDT: autonomy, competence, and relatedness/belongingness. To examine its viability, Vansteenkiste et al. (2008) designed an experiment in which the effect of intrinsic vs extrinsic goals was contrasted with the effect of a match or fit between people's personal goal orientations and the goals that are emphasized or valued in the immediate environment (the match-perspective or fit hypothesis; Pervin, 1968). Results showed that the hypothesis that students pursuing intrinsic goals will score higher than students pursuing extrinsic goals on the dependent measures (i.e., autonomous motivation, conceptual learning, rote learning) was confirmed, and the hypothesis predicting that students whose goals match the

goals of the experimental goal condition would score higher on the dependent measures was rejected.

The Motivational Consequences of FO

To date, our research on the motivational effect of FO relates to three criteria, each relevant to the development of adolescents and emerging adults. The three are academic achievement, resilience, and achieved identity. Although conceptually different, they are all indicated by behaviors and beliefs and therefore the rationale underlying the effect of FO on each bears some similarities. Specifically, the effect of FO on each is explained by two principles. One is *perceived instrumentality* (Husman and Lens, 1999; Nuttin and Lens, 1985), i.e., understanding the instrumentality of present behavior for the fulfillment of future hopes, goals, and plans. The second pertains specifically to the behaviors and processes described by the three-component FO construct.

Thus, it is not just being concerned about the consequences of present behavior for one's future (Strathman et al., 1994), or having a positive attitude toward the future. Instead, these processes are domain specific and involve activities indicating each of the three component variables. For the motivational component, they are appraising the *value*, considering the probability of materialization (*expectance*) of hopes (and the goals ensuing form them), of a specific domain and one's *control* over it. For the cognitive representation component, these activities are developing *hopes* and *fears* associated with it. Finally, for the behavioral component they are actively exploring its suitability for oneself and going through a process of decision making. Jointly, they prompt behaviors leading to academic achievement and resilience, and beliefs and behaviors indicating achieved identity.

Findings supporting the effect of the three-component FO construct on each of the three criteria are presented below. FO is assessed by a self-report battery consisting of an open-ended protocol in which respondents list their hopes and fears for the future (the hopes and fears questionnaire), and two Likert-type questionnaires estimating all empirical variables for each life domain (prospective life course questionnaire, my future questionnaire).

The Effect of FO on Academic Achievement

For children, adolescents, and emerging adulthood students, academic achievement is an indicator of competence and adjustment. Particularly for adolescents and emerging adults, it is also an essential condition for successfully engaging in adult roles. Data collected in the last decade and analyzed by means of structural equation modeling (SEM) confirmed the hypothesis about the effect of the three-component model of FO on academic achievement for several age and cultural groups. These groups consist of Muslim, Druze, and Jewish 11th and 9th graders and emerging adults (Seginer, 2009). For each of these groups, the model is satisfactorily estimated. Nonetheless, the findings also indicate domain specificity and culture variations.

Thus, the FO competence domains (i.e., higher education, work, and career) explain a higher percentage of the variance of academic achievement (reported by the participants' schools) than does the relational domain (marriage and family). In fact, the effect of marriage and family on academic achievement is significant for only two groups: the Muslim girls in Israel, and ultraorthodox Chabad Jewish girls (Seginer, 2009). However, the effect is *negative* for the Muslim girls and *positive* for the Chabad Jewish girls. Underlying these findings is the cultural meaning of marriage and family for these two cultural groups.

In the Muslim tradition girls should marry early, devote themselves to the family, and stay close to home. Although with growing numbers of educated Muslim women and economic family needs, the number of women holding a paid job has increased and stands at 21% (vs 60% among Muslim men, Israel Central Bureau of Statistics, 2010), girls still feel the pressure. They worry that early marriage will interfere with their desire for higher education, which they regard as "a weapon in women's hands" (Seginer and Mahajna, 2012). The importance Muslim girls in Israel attribute to higher education must be considered in light of two conflicting forces: its high promise for emancipated life and the strong pressure exerted by their families and communities toward early marriage. This tension is voiced by the girls' hopes and fears narratives. "For me marriage is very important but not at the expense of the girl's education. Marriage is inescapable but it has its conditions and criteria. Therefore, my hope is first study and only later on get married" (Seginer and Mahajna, 2004: p. 132). "Regarding marriage, I don't think about it now because I want to complete my education first" (Seginer, 2009: p.170).

In the ultraorthodox Jewish tradition too marriage and family are of high value and girls (as well as boys) are expected to marry early. However, for two reasons marriage and education do not conflict but rather complement each other. Given that men devote themselves to religious studies, women are responsible for bringing up the children and – by holding a paid job – for the family income. With better education, they will give their children a better education and get a better job. The girls' awareness of the importance of academic achievement for fulfilling their traditional responsibilities is echoed in their future hopes and fears narratives. "With God's help I would like to have high grades in order to have a profession and so with God's help my future husband will devote himself to religious studies." "Graduate from high school with very high grades, get a high psychometric score, study at the Chabad Teachers' college, with God's help marry a Chasidic husband, become an emissary, and have many well-educated Chasidic children."

The Effect of FO on Resilience

Common to the different conceptualizations of resilience is the tendency to engage in behaviors that indicates successful adaptation to serious adversity (Masten, 2014). Its nature varies according to the type of adverse circumstances and the individuals' developmental period, gender, and sociocultural milieu. For adolescents diagnosed as at-risk and placed in institutional care ('youth villages') with adolescents similarly diagnosed, resilience is indicated by overcoming deviant behavior, accepting the authority of adult figures, particularly teachers and the youth village care team, and participating in social and educational activities in the youth village.

Research on the effect of FO on resilience is at its beginning. The findings presented here are the result of one study about

at-risk youth who for adverse family circumstances live and attend school in residential care known in Israel as youth villages. Resilient behavior was assessed by the response of the youth village care team to four scales pertaining to aggressive behavior, deviant behavior, acceptance of adult authority, and active participation in the youth village social and educational activities. SEM analyses show a satisfactory fit with the theoretical model in which the three-component FO affects resilience. However, the extent to which FO explains the variance of resilient behavior varies. It is highest (17%) for continued education and lowest (4%) for work and career, possibly because for these youths work is not a pathway to career. The marriage and family domain explains 8% of the variance of resilience.

The Effect of FO on Achieved Identity

Identity has multiple definitions, but a common theoretical origin. We owe the term and the richness of its conceptualization to Erikson. The analysis of the effect of FO on achieved identity draws on his proposition, "The young person, in order to experience wholeness, must feel a progressive continuity between that which he has come to be during the long years of childhood and that *which he promises to become in the anticipated future*…" (1968: p. 87, *italics* added). However, while Erikson contended that identity "comes to its ascendance" (1968: p. 95) during adolescence, social circumstances in industrial societies have resulted in a postponed entrance to adulthood via the period of emerging adulthood. Therefore, here we report of research carried out with emerging adults.

Of the three studies we describe here, two were carried out with Israeli Jewish and one with Belgian emerging adults; one is cross-sectional and two are longitudinal. Given the multiple conceptualizations of FO and FTP and identity formation, each study has used different conceptualizations. Nevertheless, their findings lead to common conclusions, indicating that while concurrently FO precedes identity development, across time FO and FTP and identity are reciprocally related.

The study (Seginer, 2009) examining the effect of FO on identity concurrently assessed the motivational and behavioral components of FO regarding the two universal adult roles: work and family. Findings showed that for both future life domains, the effect on identity was strongest for expectance (a motivational variable) and commitment (a behavioral variable).

Next, (Seginer and Ablin, in preparation) FO was conceptualized and assessed by all three FO components for the two adult role domains. Identity was assessed by the objective measure of ego identity in adolescence assessing two identity domains: ideological and relational. Drawing on Erikson's continuity proposition, the hypothesis was that across time (18 months), FO has a direct effect on achieved identity. Testing the hypothesis separately for the effect of the work and career FO on ideological identity (instrumental) and of marriage and family FO on relational identity (relational), called for a modified model. Showing satisfactory goodness of fit, this model indicated that while in both Time 1 and Time 2 FO had a direct effect on achieved identity, across time; across time, they are reciprocally related. Testing a similar question using different conceptualizations and research instruments, Luyckx et al. (2010) found that over a 4 months period, for Belgian college students FTP and identity had a reciprocal effect. SEM testing three alternative models in which FTP and two present time perspective (PTP) scales were included (FTP and PTP affect identity, identity affects FTP and PTP, FTP and PTP and identity are mutually related), showed the best fit was obtained for the mutual effect of FTP (and PTP) and identity. Moreover, the reciprocal model also shows that Time 1 FTP has the highest positive effect on commitment and the highest negative effect on the diffuse-avoidant style.

Summary: Conditions for Prompting the Motivational Consequences of FTP and FO

By way of summary it is important to note that not all future thinking motivates present behavior. Indefinite and non-committing general goals, self-enhancing possible selves (Oyserman et al., 1995), and hopes and fear pertaining to existential domains (Seginer, 2009) have low motivating power. Moreover, positive fantasies have a negative effect on academic achievement among lower class students (Kappes et al., 2012). These findings make it especially important to highlight condition that enhances the motivational qualities of FTP and FO.

Terminology and conceptual differences notwithstanding research emanating from both approaches highlights three conditions enhancing the motivating qualities of FTP and FO. One relates to temporal proximity: The closer the distance between the task to which FO relates and present behavior, the stronger is the effect of FTP and FO on present behavior. However, as indicated particularly by FTP research, individuals with extended FTP perceive distant goals as psychologically closer. Hence, they attribute higher value to distant goals and perceive the instrumentality of behavior leading to the fulfillment of these goals more clearly than do individuals with short FTP.

The second condition relates to content similarity between FTP or FO under consideration and present behavior. High similarity – or *endogenous instrumentality* – enhances the motivational power of FTP and FO, whereas low similarity – or *exogenous instrumentality* – does not. The third condition also relates to content. Specifically, it is the content of future goals as arousing autonomous (rather than controlling) motivation. Future goals arouse autonomous motivation if these goals are personally important or perceived as congruent with the person's true self, so that their pursuit is characterized by identified or integrated regulation.

While these conditions relate to individuals' characteristics and the nature of goals, a fourth condition relates to the sociocultural context. As indicated by FO findings, in comparison to middle class Jewish adolescents, the effect of higher education FO on academic achievement is higher for underprivileged adolescents. Aware of social and economic obstacles awaiting them in fulfilling higher education goals, they perceive the instrumentality of academic achievement for materializing their higher education hopes.

Gaia

Abstract

The Gaia theory suggests that the Earth displays emergent self-regulation of key surface parameters such as temperature and oxidation state due to feedbacks between living beings and rocks, atmosphere, and water. This article gives a scientific outline of the theory and considers some of its philosophical and societal implications.

In the early 1970s, the English scientist and inventor, James Lovelock (helped later on by the American evolutionary biologist Lynn Margulis) postulated the Gaia hypothesis, which stated that life on Earth is a global phenomenon which drives a planetary self-regulating system that binds the atmosphere to the continents and oceans in a quasiphysiological, self-regulating process (Lovelock, 1972, 1979; Lovelock and Margulis, 1975). Lovelock was inspired to conceive of the Gaia hypothesis while contributing to NASA's efforts to find life on Mars (Lovelock, 1965). As a theory of evolution, Gaian thinking in science holds that life forms have coevolved with their environment in such a way that environmental conditions have remained suitable for life over geological time despite a continually increasing influx of solar energy and a variable input of carbon dioxide (a greenhouse gas) from volcanic activity.

The Gaia theory, Lovelock's more recent, more sophisticated elaboration of his initial insight, posits that feedbacks between living organisms and rocks, atmosphere and water regulate the planetary surface environment, which would otherwise be rendered uninhabitable by the forces of planetary physics and chemistry (Lovelock, 1988). The evidence put forward for the Gaia theory draws attention to the fact that the chemical composition of the Earth's atmosphere has stayed remarkably constant over the last 545 million years or so, and is quite unlike the composition that would be expected in the abiological steady state of a lifeless planet. The geological record suggests that temperature has remained within the narrow limits that life can tolerate over geological time, since neither global freezing nor exceedingly hot conditions have prevailed for long on the planet, if at all. Mean surface temperature has probably never departed for geologically significant periods from the range 5–50 °C (Lovelock and Whitfield, 1982). The Gaian perspective has spawned new avenues of scientific inquiry aimed at furthering the understanding of biogeochemical cycles, especially in the atmospheric sciences. For example, the importance of methane in climate change came to be taken seriously with the recognition that organisms emitting this gas play a vital role in determining the surface temperature of the planet. The Gaia theory also led to the discovery that organisms influence planetary temperatures by accelerating the weathering of silicate rocks such as granite and basalt, and by emitting gasses that seed planet-cooling clouds over both land and ocean.

More recent scientific work inspired by the Gaia theory strongly suggests that there have been several hugely important but highly improbable global revolutions during the 3500 million years that have totally reconfigured our planetary environment in ways that paved the way for today's multicellular biosphere (Lenton and Watson, 2011). This suggests that planets with high atmospheric oxygen and multicellular organisms as seen on Earth might be very rare in the cosmos.

Lovelock (1988) coined the term geophysiology to denote an emerging systems approach to earth science that might assist in furthering understanding of the implications of human interventions into climate and biogeochemical cycles in ways that could threaten the current configuration of the planetary operating system. By using the term geophysiology, Lovelock distanced himself from teleological criticisms and the mysticism that has come to surround the notion of Gaia. For Lovelock, Gaia is a quasiliving entity that has the capacity for global level self-regulation operating according to cybernetic principles, which like a thermostat, does not require will or sentience.

Gaia caught the public imagination in the 1980s, along with an emerging conviction in the scientific community that the global environment was being seriously affected by human action (Ruse, 2013). For environmentalists, Gaia became a symbol of the need for promoting an ecocentric view of the world around us, in contrast to the dominant anthropocentric view. For many, Gaia also became an argument that cooperation rather than competitiveness was needed to unite humanity in the face of threats to the global environment and an argument for alternative ways of living. It is important to distinguish between the Gaia theory as mainstream science, and Gaia, the popular symbol of environmentalists, which underpins a call for an ecological egalitarianism to end all forms of human domination of

nature (Serafin, 1988). A considerable literature has developed exploring Gaia both as a scientific concept and as an ethical, philosophical, and sociological proposition. Debates in the literature about Gaia have been set increasingly in the historical context of an emerging science of the biosphere. Gaia is seen as an elaboration of ideas put forward by the Englishman James Hutton who first proposed Earth to be a living organism in 1785 and the Russian Vladimir Vernadsky who, in the early part of the twentieth century, realized the importance of life as a geological force.

Abstract

An overview of the life, scientific interests, and historical legacy of the Victorian scientific polymath, Sir Francis Galton (1822–1911). Galton's chief scientific contributions stemmed from a dual fascination with heredity and quantification. He made significant contributions to the sciences of heredity and evolutionary biology – devoting much of his career to the statistical analysis of physical and mental traits – and he played a critical role in the formulation of the statistical procedures of correlation and regression analysis. In addition, he was active in advocating 'eugenics,' the practice of selective human breeding, a term he coined in 1883. Finally, Galton was responsible for several advances in the field of meteorology, including discovering and naming the anticyclone in 1862.

Francis Galton was born in Birmingham on February 16, 1822, the third son of Samuel Tertius Galton, a wealthy banker whose fortune was mainly derived from his father's musket manufactories. Francis was also the grandson of Erasmus Darwin, in whose scientific and evolutionist footsteps he was later to follow. However, he was originally destined for a career in medicine. Aged 16, at his father's behest, Francis enrolled as a medical student at the Birmingham Free Hospital, from where he moved to King's College, London to study medicine in 1839, and to Trinity College, Cambridge in 1840 to read mathematics. Having achieved only a pass degree at Cambridge, largely due to the first of the mental breakdowns that punctuated his career, Galton continued with his medical instruction despite a growing aversion to it. Coming into a substantial fortune on the death of his father in 1844, he immediately abandoned medicine and spent several indolent years 'hunting, fishing and shooting.' Then, in 1850, he led and financed an exploratory expedition to South-West Africa (modern Namibia). On his return, in 1852, Galton was lionized by the scientific establishment. And having achieved this entrée into the scientific community, gradually he established himself as one of Victorian Britain's most respected men of science. He was knighted in 1909.

Francis Galton is now remembered chiefly for his innovations in the field of statistics and for advocating the practice of eugenics. But his interest in both of these areas initially arose from an attempt to provide scientific evidence for the inheritance of human mental attributes. In fact, Galton devoted most of his professional energies to investigating varied aspects of heredity, a predilection largely inspired by reading Charles Darwin's (his half-cousin) *The Origin of Species* in 1859. Throughout his career, Galton's views of mind and morality were unequivocally materialist and evolutionary. In 1865, he published an article in two parts, under the heading 'Hereditary talent and character,' that were later expanded into his first book on the subject of mental heredity, *Hereditary Genius* (1869). In each of these publications he sought to show that the pedigrees of geniuses contain considerably more forebears of high social distinction than the lineages of those with mediocre parentage. Galton was aware that any positive results might instead suggest the importance of nepotism and unequal access to education. But on the basis of several ingenious – albeit less than convincing – arguments he insisted that for the highly intelligent neither education nor preferment are necessary for the fulfillment of their inborn intellectual potential. This permitted him to interpret any instance of relatedness among the eminent as being due to shared heredity.

Having presented detailed pedigrees for several hundred eminent men Galton calculated that 50 percent of illustrious individuals have at least one distinguished relation. On this basis he concluded that heredity is the primary determinant of intellectual ability. He also devoted a section of *Hereditary Genius* to estimating, in terms of the overall stock of hereditary intelligence, the 'comparative worth' of different nations and races. Galton reproduced the typical mid-Victorian conception of a racial hierarchy stretching from the Caucasian to the Negroid, although he argued that the ancient Athenians were appreciably more intelligent on average than any modern civilized nation.

During the 1870s, Galton continued his researches into human mental heredity. In 1874 he issued questionnaires to leading men of mid-Victorian science, hoping to shed light on the relative importance of 'nature and nurture' in their choice of vocation. Predictably, his data interpretation was prejudiced in favor of a hereditarian explanation. In 1875, although he had no conception of the modern distinction between monozygotic and dizygotic twins, Galton turned to the phenomenon of twinning as a means of delineating between heredity and environment. He collected the life histories of pairs of like-sexed twins and sought to determine if those that were similar at birth and in childhood became unlike upon leaving their similar home environments. He also asked if like-sexed twins that were dissimilar at birth subsequently became more similar in the shared home environment. In both cases Galton concluded that character had been formed prior to birth and had thereafter shown only limited flexibility in response to environmental pressures.

On the basis of his studies of heredity, Galton proposed the peremptory regulation of human breeding so as to maximize the biological quality of the nation. In 1869 he recommended the confinement of the socially undesirable in 'celibate monasteries or sisterhoods,' and the creation of incentives for the intellectual elites to reproduce more

frequently. The term 'eugenics' was coined in 1883 by Galton from the Greek *eugenes* meaning 'good in stock.' Yet, eugenics was widely considered impracticable during the 1860s and it was only during Galton's last decade that he began championing the idea. By then, foreign challenges to Britain's industrial and mercantile hegemony, and fears of an increasingly volatile urban underclass had rendered eugenics an appealing notion to many *fin-de-siècle* Britons. In 1908, after initial reluctance occasioned by his advanced age, Galton became President of the newly formed Eugenics Education Society.

Political considerations bulked large in Galton's advocacy of eugenics. Running through his work on heredity and eugenics, and becoming more pronounced with time, was a strongly elitist conviction that the vast majority of the lower classes were sexually profligate and irremediably inferior to the higher social classes. Accordingly, he expressed the fear that the lower classes were out-breeding the 'respectable' classes. Moreover, Galton's predilection for studying intelligence and his commitment to enhancing the reproductive rate of the most intelligent are symptomatic of his upbringing as a member of the Victorian professional middle class. This was a social stratum that set great store by intellectual accomplishment and produced many of the century's foremost social reformers, commentators and scientists: Galton unconsciously celebrated the core values and accomplishments of this important social group. In advocating eugenics he was also influenced by the widely held belief in the possibility of human perfectibility – of which his grandfather Erasmus Darwin had been a leading exponent – and by the potent mid-Victorian ideologies of human and social progress advanced most forcefully by his friend and colleague Herbert Spencer. Lastly, Galton's eugenic thought reflects the growing impetus among Victorian life-scientists for making their discipline practically useful to the state.

In the context of studying the inheritance of human mental and bodily traits, Galton emerged as an innovative statistician. His maxim was 'Whenever you can, count,' and his researches suggest a man with an almost obsessive compulsion to do so. In *Hereditary Talent* and *Hereditary Genius*, Galton became the first person to employ the Gaussian error curve in classifying human *mental* attributes. Although his use of statistics was at this stage rudimentary, he accomplished the important step of measuring – and focusing almost entirely upon – statistical variation. This aspect of the normal curve had not received much attention from his contemporaries (with the exception of the Belgian astronomer and statistician Adolphe Quetelet), many of his predecessors regarding variation from the mean as 'error' rather than a natural phenomenon worthy of investigation. All of Galton's major statistical insights stemmed from this concern for statistical spread as opposed to averages alone. In particular, his work was pivotal in the development of both the correlation co-efficient and regression analysis. Galton formulated a graphical method to measure correlation in 1886 by plotting the distributions of both variables, and two years later he devised an 'index of co-relation.' In fact, his computational procedures for 'co-relation' involved measuring the slope of the regression line and producing a measure of the regression coefficient. The mathematical underpinnings of correlation were developed more fully by his admirer and first biographer, Karl Pearson. From Galton's idea of regression, Pearson also developed a statistical system for the linear production of two continuous variables.

Galton's role in the development of regression analysis is more ambiguous. As a means of studying the mathematics of hereditary variation, during the late 1870s Galton began to breed sweet peas. He found that the F_1 generation peas were, on average, only a third as extreme in any given quality as the parental generation. Thus, through his breeding experiments, Galton had stumbled upon the statistical principle of regression. However, he always assumed that the phenomenon of regression related to a fundamental physiological process, and his explanation for it was biological rather than statistical. Galton asserted that each individual is composed of distinct hereditary units derived both from parents and from earlier ancestors. In each generation a random selection of the ancestral and parental hereditary material is made, such that only some of the total complement of hereditary units are actually expressed in each offspring. Galton believed that, from a purely probabilistic point of view, the entire hereditary material – stretching back several generations – would on average be close to the population mean. However, because only a random selection of hereditary units gain expression, it is possible for more extreme characteristics to be produced. Regression occurs when, as is likely, the more mediocre hereditary units regain supremacy in the following generation. This conception of the nature of heredity led to Galton's formulation of the 'ancestral law of heredity,' a law stipulating that any two parents together contribute approximately one-half of the total hereditary material of the offspring, the four grandparents one-quarter, and so on until the proportions become vanishingly small. Galton believed this law to describe the actual hereditary composition of each individual and the model formed the basis of his statistical treatment of heredity in *Natural Inheritance* (Galton, 1889). During the twentieth century, 'Galton's law' would be eclipsed by the advent of Mendelian genetics.

'Galton's law' may not have long survived the rediscovery of Mendel's work, but Galton has been credited with anticipating August Weismann's concept of the continuity of germplasm. Unlike Darwin and the majority of his contemporary life-scientists, from as early as 1865 Galton was largely dismissive of the notion of the inheritance of acquired characteristics. During the early 1870s he experimentally tested Darwin's theory of 'Pangenesis' – according to which bodily tissues throw off the germ cells from which offspring are produced – by transfusing blood among different varieties of rabbit. His predictable conclusion brought no pleasure to Darwin, and Galton's 1871 rejection of Pangenesis in *Nature* elicited from him a swift rebuke. Subsequently, Galton's resistance to the inheritance of acquired characteristics hardened. In the models of hereditary transmission he published during the first half of the 1870s, he claimed that the 'patent' hereditary units that become bodily structures only rarely return to the reproductive organs to be transmitted to progeny. In contrast, the 'latent' elements remain in the testes and ovaries ready to be transmitted to the next generation. In this rather circumscribed sense his hereditarian model did foreshadow Weismannism.

However, aside from the many technical inconsistencies between Galton's and Weismann's concepts of heredity, it is important to note that after 1875 Galton departed significantly from the position outlined above. He gradually came to appreciate that his case for the continuity of traits between parents and offspring was weakened if it were assumed that the latter inherited only the former's latent elements and very few of their patent elements. As a result, by the late 1880s Galton was writing of patent and latent elements as being equally heritable. Whilst he remained only mildly sympathetic to the notion of the inheritance of acquired characteristics, he had abandoned his earlier emphasis upon the near-absolute separation of bodily from reproductive cells.

Galton's dual fascination with heredity and quantification also generated an interest in anthropometry, the measurement of bodily morphology. During the 1870s, appalled that so little was known about the physique of the British people and fearful that a biological decline was already in progress, Galton sought to obtain anthropometric information on children from different social classes. Subsequently, he became a member and later chairman of a British Association committee investigating occupational disparities in size and weight. Throughout his involvement with this committee Galton was convinced that heredity was the chief determinant of anthropometric variation. As a means of procuring raw data from which to study hereditary transmission in humans, in 1884 he set up an elaborate anthropometric laboratory at the International Health Exhibition in London. Equipment was installed to measure the height, weight, breathing-capacity and, *inter alia*, the strength of pull of members of the public. Also measured were such qualities as keenness of sight, hearing, and color discrimination.

These last tests reflect Galton's interest in what he dubbed 'psycho-physics,' the scientific investigation of mental phenomena. Generalizing his earlier conviction that individual nurture is a subordinate force to heredity, he emphasized aspects of unconscious cerebral function in which the 'will' seems to play little if any role. In his 1883 *Inquiries into Human Faculty*, Galton described and, where feasible, quantified a range of unconscious and sensory phenomena, including number forms, visual imagery, color associations, visions, and sensory awareness among the blind. He also documented the results of his introspective investigations into the power of the individual will. In the course of these studies, Galton devised the method of 'word-association' with which to demonstrate his claim that very few thoughts or actions are ever the spontaneous product of the will but relate to desires, ideas and associations of which we have little conscious awareness.

In addition, Galton was a pioneer in the design and employment of composite photography. He hoped that through superimposing numerous photographic portraits on top of each other he would be able to discern the common hereditary features shared by families or groups. His main work in this area involved an attempt to discover the physiognomical indices of different forms of criminality from a series of photographs supplied by the Inspector of Prisons. To his disappointment, Galton found no evidence of distinctive criminal types. However, this interest in hereditary variation, measurement and their relevance to criminal investigations also culminated in his extensive study of fingerprints. Galton was not an innovator in this field but his several publications on the subject drew attention to the enormous value of fingerprints as a means of personal identification.

Although it is clear that most of Galton's scientific work stemmed from his early fascination with heredity, his scientific curiosity was nonetheless polymathic in breadth. Over the course of half-a-century's involvement with the Royal Geographical Society, he was able to make significant contributions to the expeditions of such explorers as R. Burton, J. Speke, and J. Grant, and he worked hard to place geography on a more scientific footing. As an active meteorologist he was instrumental in the construction of weather maps and was responsible for discovering the 'anticyclone' in 1862. Finally, he was an enthusiastic advocate of establishing scientific activity as an occupation of dedicated, professional and, if necessary, salaried, researchers. Alongside T. H. Huxley, John Tyndall, Joseph Hooker, and others, he campaigned vigorously to free science from the limitations imposed by religious orthodoxy. To this end, many of Galton's works carried thinly veiled attacks on theology and the Church, most strikingly his 1872 attempt to prove statistically that prayer is inefficacious.

In retrospect, there can be little doubt that Galton gave an important impetus to the scientific study of heredity and the development of psychometric testing. Despite the shortcomings later revealed in his own work, he was the first to subject human intellectual attributes to systematic numerical analysis. With the aid of W. F. R. Weldon and Karl Pearson, he was also intimately involved with establishing a statistical approach to the study of evolution. Perhaps Galton's most lasting contributions to science arose from his statistical breakthroughs of the 1870s and 1880s. Statistical procedures derived from his initial insights are now indispensable to both the natural and the social sciences. More practically, his private wealth enabled him to set up a Eugenics Research Office at University College London in 1904. He honored and extended this commitment upon his death (on January 17, 1911) when he created the Galton Professorship of Eugenics and named Karl Pearson as the Chair's first holder.

Any summary of Galton's legacy must recognize that eugenic ideas were implemented after his demise with horrific consequences, and that the hereditarian ideologies he promoted have often been used as means of social, sexual and racial oppression. In the wake of the Nazi atrocities of the 1930s and 1940s, and of the civil rights movements of the 1960s and 1970s, Galton's stock as an important scientific figure has declined rapidly. However, in the interests of a proper understanding of the past, it should be pointed out that to implicate Galton in the rise of twentieth-century eugenic practices is to over-personalize a complex series of events and set of national circumstances. Eugenic measures were linked to a wide range of social, economic and political factors against which Galton's advocacy is scarcely more than trivial. Furthermore, even in 1865 the notion of selective human breeding was far from novel: Galton's originality lay

only in buttressing the idea with apparently rigorous scientific research.

Abstract

We study situations of conflict of interest, which we call 'games.' Both noncooperative and cooperative games are considered, and several types of solution concept are defined and analyzed. For noncooperative games, optimal strategies and equilibrium *n*-tuples are defined. For cooperative games, such concepts as the core, the Shapley value, and the bargaining set are treated.

Obviously, game theory is applicable to parlor games and warfare. Other applications of game theory to economics, political science, and evolutionary biology are given and several examples are worked out in detail.

Game Theory is the mathematical study of situations of conflict of interest. As such it is applicable to parlor games (hence its name), but also to military and economic situations, and, to a lesser extent, to situations in other social sciences. Game theory studies three general phases in the process of interaction: the choice of *strategies*, the formation of *coalitions*, and *bargaining* within coalitions.

As concerns ethics, game theory is useful as an arbitration technique for bargaining problems (Section Two-Person Cooperative Games) and, in distributive justice, for allocating the gains from cooperation (Section *n*-Person Games). Conversely, it can be used to design rules (e.g., assignment of weights for voting in a parliament whose members represent constituencies of different sizes) so that normal play of a game will lead to a 'fair' outcome.

Representation of Games

Games are represented in several ways. Among these are the extensive form, the *normal* form, and the *characteristic* function.

The Extensive Form

The extensive form of a game is a tree (graph) which exhibits the logical sequence of moves in a game, showing the order in which players move, the information they have when making a move, and, for chance moves, the associated probabilities.

Example 1 – Matching Pennies

Player I chooses either H (heads) or T (tails). Then player II, in ignorance of I's choice, chooses either H or T. Now, if both choose H, I pays \$3 to II; if both choose T, I pays \$1 to II. Otherwise, II pays \$2 to I.

This game is represented by the tree in **Figure 1**. The game starts at vertex A, which 'belongs' to player I. From here, I's choice leads to either B or C, both of which belong to player II. The shaded area joining these two vertices is used to represent II's lack of information: when he moves, he knows he is at one of these two vertices, but cannot distinguish between them. Technically, vertices B and C belong to the same *information set*. From either of these, II has two alternatives, H and T. After this, the game terminates at one of the vertices, D, E, F, or G. A vector with two components is assigned to each of the terminal vertices: these are the payoffs. For example, the $(-3, +3)$ assigned to vertex D means that player I loses \$3 and II wins \$3.

Example 2

Consider the same game as in Example 1, with the sole change that player II is allowed to make his decision after seeing what player I has chosen. All else is as in Example 1.

This game is shown in **Figure 2**. The only difference lies in the fact that vertices B and C are not in the same information set; in this game, player II can distinguish between them.

In Example 2, note that all information sets consist of a single vertex. In such a case, the game is said to have *perfect information* (a situation in which a player knows all moves that have been made). The game in Example 1 does not have perfect information, nor does the one in the following Example 3.

Example 3 – Rudimentary Poker

Chance gives player I either a high card (H) or a low card (L), with probabilities of 0.2 and 0.8, respectively. Player I, seeing the card, can bet (B) or pass (P).

If player I passes, the game terminates immediately. Player II pays \$1 to I if I has H, while I pays \$1 to II if I has L. If player I bets, then II can call (C) or fold (F). If player II folds, then he pays \$1 to player I. If II calls, then II pays \$3 to I if I has H, and I pays \$3 to II if I has L. Recall that, in deciding to call or fold,

Figure 1 The extensive form of the game in Example 1.

Figure 2 The extensive form of the game in Example 2.

player II knows whether I has bet or passed, but not whether she is holding H or L.

This game is represented in Figure 3. Note that at the chance move, the probabilities are specified; we assume that both players know the probabilities. Any attempt to change the probabilities (e.g., by stacking the deck) is considered cheating and is illegal. Note also that two vertices (E and F) are in one information set; hence player II's information is imperfect.

The Normal Form

While the extensive form representation of a game gives us a very good description of the actual play of a game, it is easier to analyze the game (as regards maximizing winnings) with the normal form. This is based on the notion of a *strategy* (a rule that tells a player what to do at each position).

A strategy for a given player is a comprehensive set of rules telling a player which alternative to choose in each information set. Note that a strategy may be good or bad, and that the rules that make up a strategy do not have the force of laws: a player may disregard such a rule if he/she wishes so.

To go back to Example 1, we see that player I has one information set (vertex A) with two alternatives. Thus he/she has two strategies, H and T. Similarly, player II, with one information set (B and C) and two alternatives there, has two strategies, also called H and T.

Figure 3 The extensive form of the game in Example 3.

In Example 2, player I has once again two strategies, H and T. Player II, however, has two information sets, with two alternatives in each. Thus player II has four strategies: HH (always call H), HT (call H at B, call T at C), TH (call T at B, call H at C), and TT (always call T).

In Example 3, player I has two information sets, with two alternatives at each, and thus four strategies: BB (always bet), BP (bet at B, pass at C), PB (pass at B, bet at C), and PP (always pass). Player II has only the two strategies, C and F.

In a given game, suppose each player has chosen a strategy. If the game has no chance moves, several players' strategies will entirely determine the course of play, and hence the outcome and payoff of the game. In a game with chance moves, the outcome will also depend on the chance moves. By hypothesis, however, the probabilities at the chance moves are well determined. Hence a choice of strategies will determine, up to a probability distribution, the outcome of the game. It is thus possible to calculate the mathematical expectation of the payoff. In other words, the expected payoff of the game is a function only of the strategies used by the players. This function, usually shown as a table or matrix, is the *normal form* of the game.

The normal form of the game in Example 1 is the matrix

$$\begin{array}{c} \\ \mathrm{H} \\ \mathrm{T} \end{array} \begin{array}{c} \begin{array}{cc} \mathrm{H} & \mathrm{T} \end{array} \\ \begin{pmatrix} (-3,\ 3) & (2,\ -2) \\ (2,\ -2) & (-1,\ 1) \end{pmatrix} \end{array}$$

By convention, in two-person games, the normal form is a matrix, with rows representing player I's strategies and columns representing those of player II.

The game of Example 2 is represented by

$$\begin{array}{c} \\ \mathrm{H} \\ \mathrm{T} \end{array} \begin{array}{c} \begin{array}{cccc} \mathrm{HH} & \mathrm{HT} & \mathrm{TH} & \mathrm{TT} \end{array} \\ \begin{pmatrix} (-3,\ 3) & (-3,\ 3) & (2,\ -2) & (2,\ -2) \\ (2,\ -2) & (-1,\ 1) & (2,\ -2) & (-1,\ 1) \end{pmatrix} \end{array}$$

It may be noted that, at each cell of the matrix, the sum of the two entries is equal to 0. The reason for this is that, in each of our examples, money is transferred directly from one player to the other without any external credits or debits for either player. Such games (where one player loses whatever the other one wins) are known as *zero-sum games* (one in which the sum of payoffs to all players is always zero). In a two-person zero-sum game, it suffices to show player I's payoff, since the payoff to player II is always its negative. Thus, the normal form of a finite two-person zero-sum game is a matrix whose entries are, by convention, the payoffs to player I.

In the game of Example 3, suppose player I chooses BB (always bet) while player II chooses C. In that case, player I has a 0.8 probability of losing \$3, and a 0.2 probability of winning \$3. Thus I's expected payoff is $0.8(-3) + 0.2(3) = -1.8$. Other payoffs are calculated similarly, giving us the normal form

$$\begin{array}{c} \\ \mathrm{BB} \\ \mathrm{BP} \\ \mathrm{PB} \\ \mathrm{PP} \end{array} \begin{array}{c} \begin{array}{cc} \mathrm{C} & \mathrm{F} \end{array} \\ \begin{pmatrix} -1.8 & 1 \\ -0.2 & -0.6 \\ -2.2 & 1 \\ -0.6 & -0.6 \end{pmatrix} \end{array}$$

We postpone discussion of the characteristic function until treatment of cooperative games with three or more players.

Two-Person Zero-Sum Games

As just discussed, these games represent a closed system: whatever one player wins, the other player loses. In the finite case, such a game is represented by a matrix. If player I has m strategies, while II has n strategies, then the normal form is an $m \times n$ matrix A, where a_{ij}, the entry in the ith row and jth column, is the payoff to player I if she uses her ith strategy while II uses his jth strategy. The game is a *matrix game* (a finite two-person zero-sum game in normal form).

Saddle Points

Now, player I wishes to maximize, and player II to minimize, the payoff. For Example 1, the normal form (abbreviated) is

$$\begin{array}{c c} & \begin{array}{cc} \text{H} & \text{T} \end{array} \\ \begin{array}{c} \text{H} \\ \text{T} \end{array} & \begin{pmatrix} -3 & 2 \\ 2 & -1 \end{pmatrix} \end{array}$$

and it may be seen that there is no strategy that can be considered truly 'good': whatever one player chooses, the other can win by simply 'guessing correctly.' Thus if I chooses H, then II can win by choosing H; but if so then it would be better for I to choose T; but then it would be better for II to choose T; but then it would be better for I to choose H; etc. Thus it is not clear what should be done in this game.

Contrast this with the game of Example 2, whose matrix is

$$\begin{array}{c c} & \begin{array}{cccc} \text{HH} & \text{HT} & \text{TH} & \text{TT} \end{array} \\ \begin{array}{c} \text{H} \\ \text{T} \end{array} & \begin{pmatrix} -3 & -3 & 2 & 2 \\ 2 & -1 & 2 & -1 \end{pmatrix} \end{array}$$

In this game player II has a 'sure thing' strategy in HT. Whatever player I chooses, II does at least as well with HT as with any other strategy. Thus II should always use HT. Given that II will choose HT, player I should choose T as this minimizes her losses.

Example 4

Consider the following matrix game:

$$\begin{array}{c c} & \begin{array}{ccc} \text{A} & \text{B} & \text{C} \end{array} \\ \begin{array}{c} \text{D} \\ \text{E} \\ \text{F} \end{array} & \begin{pmatrix} 4 & 1 & -3 \\ 5 & 2 & 4 \\ -1 & 0 & 6 \end{pmatrix} \end{array}$$

In this game, there is no 'sure thing,' in the sense of a strategy (for either player) which is always better than anything else. Rather, we analyze the game as follows.

If player I is cautious, then, in using any strategy, she will worry about the worst that can happen to her. This 'worst' is represented by the smallest entry in each row, namely -3 for D, -2 for E, and -1 for F. Thus caution suggests using row E.

Suppose, however, that player II figures out what player I is thinking (i.e., using row E). Then he would use column B as this minimizes the payoff in row E. But, if II is using B, this is all the more reason for I to use E (as this maximizes the payoff in column B). Thus, the pair of strategies (row E, column B) presents a very stable type of equilibrium. The value of 2 at their intersection, which is both the smallest entry in its row and the largest entry in its column, is a *saddle point* (an entry (in a matrix) which is the smallest in its row and the largest in its column).

Definition 1

In a matrix game A, the entry a_{kh}, is a saddle point if, for each $i = 1, \ldots, m$,

$$a_{kh} \geq a_{ih}$$

and, for each $j = 1, \ldots, n$,

$$a_{kh} \leq a_{kj}$$

If a matrix game has a saddle point a_{kh}, then this saddle point is a very satisfactory *solution* for the game. In fact, by using the kth row, player I expects to win at least a_{kh}; by using the hth column, player II expects to lose no more than this same amount. We say then that a_{kh} is the *value* (in a matrix game, a quantity which the maximizer can ensure herself of winning; the minimizer in turn can ensure himself against losing more than that quantity) of the game, and the two strategies (row k, column h) are *optimal strategies* (a strategy which guarantees the value). In case of more than one saddle point, the following theorem is helpful:

Theorem 1

Let the matrix game A have saddle points at a_{kh} and at a_{ij}. Then $a_{ij} = a_{kh}$, and, moreover, the entries a_{kh} and a_{ij} are also saddle points.

The importance of Theorem 1 lies in the fact that (1) players have no incentive for trying to change from one saddle point to another, and (2) if the two players try for two different saddle points, the outcome will nevertheless be a saddle point.

Mixed Strategies

While saddle points represent a very satisfactory solution for matrix games, the fact remains that, in general, such games need not have saddle points. (Note Examples 1 and 3 for games with no saddle points.) In such a case, it seems that the winner will be the one who can think one step further than the other player. ("He bluffed last time, so he will expect me to call this time, and therefore he will not bluff, so I should fold if he bets. But perhaps he knows that I am thinking this, and will bluff again, so I should call his bet. But perhaps he is thinking this, too, so….") Unfortunately, thinking two steps (instead of one) further ahead than the other might well lead to defeat. Rather than this attempt at outguessing, mathematicians have developed the idea of a *mixed strategy* (a randomization scheme for choosing among a player's pure strategies).

Consider once again Example 3. The first thing to notice is that there is no point in using either row 3 (PB) or row 4 (PP). In fact, BB is always at least as good (for player I) as PB, and sometimes better, while BP is always at least as good as PP, and sometimes better. This says quite simply that player I should always bet on a high card. The question is whether she should

bet (bluff) or pass on a low card. As mentioned above, it is important for player I to keep her opponent guessing.

To keep player II from outguessing her, player I might well decide to choose her strategy at random, i.e., in case she receives L, she might flip a coin and bluff if the coin comes up heads, or pass if the coin comes up tails. In fact this is a possibility, but it effectively seems to take away any 'free choice' that player I might have. Moreover, it is not clear why bluffing exactly half the time should be particularly good.

It turns out that, in this game, player I's best choice – in a way to be explained shortly – is to bluff one-eighth of the time, i.e., always bet if she has H, and, with L, bet with probability 0.125. Note that, in this way, she does not really give up her free choice – she chooses the probability, 0.125, in a rational way, and then lets a randomization device tell her what to do. More precisely, she chooses among her four strategies through a random mechanism which assigns probabilities 0.125, 0.875, 0, and 0 to them. This is a mixed strategy. We will use the term *pure strategy* for the rows and columns of the matrix (i.e., for what we have up to now called strategy).

Definition 2

In an $m \times n$ matrix game, a mixed strategy for player I is a randomization scheme over that player's pure strategies, or equivalently, a vector $\mathbf{x} = (x_1, \ldots, x_m)$ with nonnegative components which add up to 1. Similarly, a mixed strategy for player II is a vector $\mathbf{y} = (y_1, \ldots, y_n)$ with nonnegative components that add up to 1.

Essentially, the rationale for mixed strategies lies in the fact that player II might be able to reproduce (in some way) player I's thinking process and thus might be able to guess I's mixed strategy. However, II will not know what player I actually does since this depends on a random mechanism. Similarly, I can guess II's mixed strategy but not his actual choice of action.

Assuming player I uses the mixed strategy $\mathbf{x}$, while II uses $\mathbf{y}$, then under the assumption of independence (these two randomization schemes are carried out independently of each other), the expected payoff will be

$$\sum_{i=1}^{m} \sum_{j=1}^{n} x_i a_{ij} y_j$$

or, in matrix notation, $\mathbf{x}^{\mathrm{T}} A \mathbf{y}$.

Now, player I will try to choose $\mathbf{x}$ (among all her mixed strategies) so as to maximize $\mathbf{x}^{\mathrm{T}} A \mathbf{y}$, while II will try to choose $\mathbf{y}$ so as to minimize this same product. We then define saddle points in mixed strategies in terms of the expected payoff, i.e.,

Definition 3

A pair of mixed strategies $\mathbf{x}^*$ and $\mathbf{y}^*$ form a saddle point for game A if, for any mixed strategy $\mathbf{x}$ of player I,

$$\mathbf{x}^{*\mathrm{T}} A \mathbf{y}^* \geq \mathbf{x}^{\mathrm{T}} A \mathbf{y}^*$$

and, for any mixed strategy $\mathbf{y}$ of player II,

$$\mathbf{x}^{*\mathrm{T}} A \mathbf{y}^* \leq \mathbf{x}^{*\mathrm{T}} A \mathbf{y}$$

In Example 3, the pair of strategies $\mathbf{x}^* = (0.125, 0.875, 0, 0)$ and $\mathbf{y}^* = (0.5, 0.5)$ is a saddle point, with $\mathbf{x}^{*\mathrm{T}} A \mathbf{y}^* = -0.4$. To see this, note that, against either one of player II's pure strategies, $\mathbf{x}^*$ gives an expected payoff of -0.4. Since any mixed strategy of player II simply chooses one or the other of these two with certain probabilities, it follows that the expected payoff, if I uses $\mathbf{x}^*$, will be -0.4, no matter what mixed strategy II uses. Similarly, against player I's four pure strategies, $\mathbf{y}^*$ gives expected payoffs of -0.4, -0.4, -0.6, and -0.6, respectively. Since none of these gives I a better payoff than -0.4, none of her mixed strategies can give a better expectation. This quantity -0.4 is the *value* of the game.

The Minimax Theorem

The question obviously arises as to the existence of saddle points in mixed strategies. The following theorem, due to J. von Neumann, is probably the most important in game theory.

Theorem 2 (The Minimax Theorem)

Any matrix game has at least one saddle point in mixed strategies.

If $(\mathbf{x}^*, \mathbf{y}^*)$ is a saddle point for game A, then the strategies $\mathbf{x}^*$ and $\mathbf{y}^*$ are said to be *optimal strategies*, while the quantity

$$v = \mathbf{x}^{*\mathrm{T}} A \mathbf{y}^*$$

is the *value* of the game. There may be several saddle points, but a theorem similar to Theorem 1 guarantees that the value is unique. A *solution* of the game is a triple $(\mathbf{x}^*, \mathbf{y}^*, v)$.

It may be that the game has a saddle point in pure strategies. If so, Theorem 2 is still true because a pure strategy can always be thought of as a (degenerate) mixed strategy: one that assigns probability 1 to one of the pure strategies, and 0 to all others. Thus, the game of Example 2 has the optimal strategies $\mathbf{x}^* = (0, 1)$ and $\mathbf{y}^* = (0, 1, 0, 0)$ and value $v = -1$.

For Example 1, the reader can verify that the solution is $\mathbf{x}^* = (0.375, 0.625)$, $\mathbf{y}^* = (0.375, 0.625)$, and $v = 0.125$.

While the minimax theorem guarantees the existence of optimal strategies and a value, the problem of computing these remains. There are two well-known techniques for this. One is based on linear programming: the optimal strategies are solution vectors for a pair of mutually dual linear programs. The other technique, known as *fictitious play*, assumes that two players play the same game a large number of times; each keeps track of his or her opponent's past choices, and at each iteration, uses the pure strategy which will do best against the opponent's empirically observed strategy. A theorem due to J. Robinson shows that under such assumptions, the empirically used strategies of both players will converge to optimality.

Infinite Games

Where each player has an infinite number of pure strategies, it is still possible to define mixed strategies and optimality. Unfortunately, the minimax theorem will not always hold for such games, and where it holds, computation of the optimal strategies may be quite complicated. We will not discuss such games here.

General-Sum Noncooperative Games

As opposed to Section Two-Person Zero-Sum Games, we consider here games in which either the sum of the payoffs is

not zero or there are more than two players. For these games, cooperation may or may not be allowed. We discuss first the noncooperative case.

The number of players may be any integer $n \geq 2$; we will label them 1, 2,…, n, and let N be the set of these players.

Nash Equilibria

In normal form, each player, j, has a strategy set which we denote by $\mathbf{\Gamma}_j$. A game is represented by n payoff functions π_j, defined for n-tuples of strategies. Thus, if $\sigma_1,\ldots, \sigma_n$ are strategies for players 1,…, n, respectively, then

$$\pi_j(\sigma_1, \ldots, \sigma_n)$$

is the payoff to player j $(1 \leq j \leq n)$ for this choice of strategies. As usual, we assume each player wishes to maximize his payoff.

In this case, the analogue to the saddle point is known as a *Nash equilibrium* (after J. Nash) (an n-tuple of strategies such that no player can gain by a unilateral change). Specifically,

Definition 4

For an n-person game with payoff functions π_j, the n strategies $\sigma_1^*, \sigma_2^*, \ldots, \sigma_n^*$ form a Nash equilibrium if, for each player j $(1 \leq j \leq n)$, and each strategy $\tau \in \mathbf{\Gamma}_j$,

$$\pi_j\left(\sigma_1^*, \ldots, \sigma_j^*, \ldots, \sigma_n^*\right) \geq \pi_j(\sigma_1^*, \ldots, \tau, \ldots, \sigma_n^*)$$

(On the right-hand side of this last inequality, it is understood that only the single term σ_j^* has changed, to be replaced by τ.) Thus, no player can gain by a unilateral change of strategies.

Example 5 – The Battle of the Sexes

Player I (a woman) and player II (a man) wish to go to either a hockey game (G) or the ballet (B). Player I would prefer the game; II prefers the ballet. However, both wish to be together and will derive no utility from going to either event alone. We represent this game by

$$\begin{array}{cc} & \begin{array}{cc} \text{G} & \text{B} \end{array} \\ \begin{array}{c} \text{G} \\ \text{B} \end{array} & \begin{pmatrix} (3, 1) & (0, 0) \\ (0, 0) & (1, 4) \end{pmatrix} \end{array}$$

where, as usual, player 1 chooses the row and II the column. In each case, the first component is the payoff to I, and the second the payoff to II. It may be seen that this game has two Nash equilibria, consisting of the strategy pairs (G, G) and (B, B).

Example 6 – The Prisoner's Dilemma

In this game, due to A.W. Tucker, players I and II are prisoners, suspected of a particular felony. The prosecutor, having no hard evidence, must hope that they will confess. He therefore offers each of them a deal.

If neither confesses, both will go to jail on minor charges. If both confess, both will receive medium sentences. If only one of the two confesses, then the one that confesses will be given a suspended sentence, and the other will receive a severe sentence.

For this game, the prisoners both have the strategies confess (C) or do not confess (D). (The prosecutor is not considered a player.) The game can then be represented by

$$\begin{array}{cc} & \begin{array}{cc} \text{C} & \text{D} \end{array} \\ \begin{array}{c} \text{C} \\ \text{D} \end{array} & \begin{pmatrix} (-5, -5) & (0, -10) \\ (-10, 0) & (-1, -1) \end{pmatrix} \end{array}$$

This game has the unique equilibrium (C, C). The reason for this is that for each player, C is always better than D, *whatever the other player does*. Hence both will, presumably, confess. (This although both will be better off if neither confesses!)

Example 7 – Cournot Oligopoly

Assume there are n producers of a homogeneous good. Each firm, i, chooses the quantity q_i it will produce. The market price p of the good will depend on the total quantity produced by the n firms. Each firm wishes to maximize its profits, defined as revenue minus costs, where revenue is the product pq_i.

In the simplest case, we assume that the inverse demand function is linear, given by $p = A - Q$, and that each firm's costs are zero. Then firm i's profits are $\pi_i = (A - Q)q_i$, where $Q = \sum_j q_j$.

For this game, an equilibrium (here a Cournot–Nash equilibrium) is obtained by differentiation, maximizing each function π_i with respect to the corresponding q_i. This equilibrium gives us $q_i = A/(n + 1)$ for each firm. All firms produce the same amount, with total production $Q = An/(n + 1)$, and market price $p = A/(n + 1)$. Profits for each firm will be $\pi_i = A^2/(n + 1)^2$.

In all three of Examples 5, 6, and 7, Nash equilibria (in pure strategies) exist. In general this is not so. It turns out, however, that, when mixed strategies are allowed, equilibria do exist. The following theorem is due to Nash.

Theorem 3

Any finite n-person game will have at least one equilibrium n-tuple of mixed strategies.

This is an existence theorem, based on a fixed-point argument, and calculation can be quite complicated. For two players, a clever technique due to C.E. Lemke and A. Howson is frequently used; for three or more, an approximation technique due to H. Scarf is extremely complicated but is the only available method.

More troublesome than the problems with computation of Nash equilibria is the fact that these tend to exhibit pathologies which never occur with matrix games. For one thing, Example 5 shows that no analogue of Theorem 1 holds, even for two-person general-sum games. The given game has two equilibria, but payoffs at both equilibria are different; thus, there will be attempts by the two players to steer the game toward one or the other of the two equilibria. Moreover, if player I tries for one equilibrium, say (G, G), while II tries for the other equilibrium (B, B), the result will be the 'disaster' (G, B). There seems to be no way to choose between the two equilibria. A third equilibrium, in mixed strategies, is very unsatisfactory.

Even in cases where there is only one Nash equilibrium, as in Example 6, this equilibrium may be unsatisfactory. In fact, both players will do much better if they both employ their nonequilibrium strategy, D. There is no way that the theory of Nash equilibria can solve this problem.

Two-Person Cooperative Games

Where cooperation is permitted, much of the interest is centered on the bargaining process that takes place prior to cooperation. This is best studied in the two-person case, where the distraction of alternative coalitions is avoided.

Nash's Bargaining Model

In this model, also due to Nash, two players are to divide a 'pie' (some asset). If they can come to an agreement, this will take effect. Otherwise, neither will receive anything.

A game such as this is represented by a set S in two-dimensional space, the set of *feasible points*: if the point with coordinates (u, v) lies in set S, then players I and II can, if they so agree, obtain utilities of u for player I and v for II. It is usually assumed that S is closed and bounded above (so that infinite amounts of utility are impossible). It is also assumed that S is convex (this is a realistic assumption since, given any two outcomes, the players are allowed to randomize between them). Apart from this, a *conflict point* (u_0, v_0) is given: in case the two players cannot agree, they will receive u_0 and v_0, respectively. The conflict point will also lie in the set S, since the two players may, if they wish, 'agree to disagree.' We wish, now, a *general bargaining rule* which will assign, to each such problem, a feasible point (u^*, v^*) as a solution.

Nash lays down four axioms that the bargaining rule should satisfy. These axioms, explained further on, are Paretooptimality (N1), independence of irrelevant alternatives (N2), invariance under linear transformations of utility (N3), and symmetry (N4).

N1 states that if point (u^*, v^*) is the solution to a problem with feasible set S, then there can be no point (u, v) in S such that either $u > u^*$, $v \geq v^*$, or $u \geq u^*$, $v > v^*$.

N2 is a rather technical axiom which states, essentially, that if point (u', v') is chosen rather than (u'', v'') for a given problem, then enlarging the feasible set (by adjoining new alternatives), and keeping the same conflict point, can never lead us to choose (u'', v'') over (u', v').

N3 is based on the idea that each individual's utility is subjective, and that there is no interpersonal comparison of utility. Moreover, each individual's utility scale is subject to linear transformations (much in the way that temperature can be measured either in the Celsius or in the Fahrenheit scale). Thus the same real-life problem has many different mathematical representations. The axiom states that the solution point should have the same real-life interpretation for all representations of the same real-life problem.

N4 states, essentially, that if the problem is symmetric (in the sense that whenever a point (u, v) is feasible, then so is (v, u), and that $u_0 = v_0$), then the solution point must satisfy $u^* = v^*$. We then obtain the following.

Theorem 4

There is a unique bargaining rule which satisfies Nash's four axioms. This rule chooses the point (u^*, v^*) so as to maximize the product

$$g(u, v) = (u - u_0)(v - v_0)$$

of the increments of the utilities, subject of course to the constraint that the point must lie in S (and, in fact, in the part of S 'above and to the right' of the conflict point).

Example 8

Players I and II are to divide the sum of \$100. Player I's utility is linear with money, i.e., her utility for x dollars is equal to x. On the other hand, player II's utility for y dollars is only $y^{1/2}$. If they cannot come to an agreement, neither will receive anything.

In this case, the conflict point is (0, 0). If player I receives x dollars, then her utility is $u = x$, while II's utility is $v = (100 - x)^{1/2}$. Thus, in an agreement, u and v satisfy the equation

$$u + v^2 = 100$$

We look then for the point which maximizes the product uv. Some calculus tells us that the maximum is at $v^* = 33.3^{1/2}$ and $u^* = 66.7$. Thus player I should receive \$66.7, while II receives only \$33.3. While this division looks strange, the point is that, because of II's utility function, the \$33.3 which he gets represents more utility to him than the \$66.7 which he does not get. This gives a bargaining advantage to player I, and she can use it to get a larger share of the \$100.

Threats

One problem with the model above lies in the determination of the conflict point. In Example 8, the situation is deliberately kept simple: failure to agree reduces each player to the status quo. In general, of course, the situation can be much more complicated. Consider a situation in which player I is a law-abiding citizen, walking along a lonely street, while player II is an armed robber. The two will 'bargain' over I's wallet, and, if no agreement is reached, player I may find herself much worse off than at the status quo. Player II, by wielding a gun, has changed the conflict point from (0, 0) to, say, $(-500, -10)$. At the new conflict point player I loses a lot; II also loses something as he would prefer to get the wallet without need for violence.

Some further points should be made here: (1) player II may have several different threats; (2) player I may herself have some available threat(s); and (3) in any case, it is not clear that the players will carry out their threats.

To take threats into consideration, Nash modified his model. In this new model, each player has finitely many threats (threat strategies) (a strategy to be used in case of no agreement). If player I uses her strategy σ_i, while II uses his strategy τ_j, they receive utilities of a_{ij} and b_{ij}, respectively. Thus the game is represented by two matrices A and B (payoffs to the two players in case of conflict) and a set S of feasible points. It is assumed that all points (a_{ij}, b_{ij}) lie in S. S might, however, be much larger than the convex hull of these conflict points.

Nash now assumes that the bargaining will go as follows:

1a. Player I chooses a (mixed) threat strategy, **x**.
1b. Player II, in ignorance of **x**, chooses a threat strategy, **y**.
2. The two players, knowing both **x** and **y**, bargain (look for a point of S on which they might agree). If they cannot agree, then they *must* use their threat strategies, obtaining (expected) payoffs of $\mathbf{x}^{\mathrm{T}}A\mathbf{y}$ and $\mathbf{x}^{\mathrm{T}}B\mathbf{y}$, respectively.

Applying Nash's previous model to this last bargaining step, we come to the conclusion that players I and II will choose that point $P^* = (u^*, v^*)$ which maximizes the product,

$$\left(u - \mathbf{x}^{\mathrm{T}}A\mathbf{y}\right)\left(v - \mathbf{x}^{\mathrm{T}}B\mathbf{y}\right)$$

subject of course to the constraints that $(u, v) \in S$ and $u \geq \mathbf{x}^{\mathrm{T}}A\mathbf{y}$, $v \geq \mathbf{x}^{\mathrm{T}}B\mathbf{y}$.

Since P^* depends on the threat strategies **x** and **y**, it follows that player I should choose **x** so as to maximize u^*, while II chooses **y** so as to maximize v^*. Now (u^*, v^*) lies on the Paretooptimal ('northeast') boundary of S, which means that as u^* increases, v^* decreases, and vice versa. The situation then is very similar to that for matrix games: there exist *optimal threat strategies* and a *bargaining value* for such games. Computation of these is generally based on the solution of a sequence of related matrix games, each of the form $A - kB$.

It should be noted that this model assumes that players *will* use their threat strategies if no agreement is reached. It is not clear just how this can be enforced. No generally accepted theory is currently available to deal with unenforceable threats.

n-Person Games

We consider now cooperative n-person games, where $n \geq 3$. The point here is that players will typically have several alternative coalitions. Thus bargaining within a coalition must be made with these competing alternatives in mind.

The Characteristic Function

The theory developed by J. von Neuman and O. Morgenstern assumes a finite set $N = \{1, 2, \ldots, n\}$ of players. A *coalition* is any nonempty subset of N (including N itself and all the one-player sets). An assumption is now made that, if a coalition S forms (or even if its members merely discuss this idea), it must consider the possibility that the remaining players – the complementary coalition $N - S$ – will form. Thus S will find itself playing a two-party game against $N - S$. Still another assumption says that utility is directly transferable (at a one-for-one rate) between members of a coalition, so that all that matters at this point is how much total utility S will gain. (Side payments within S will then adjust the several members' shares.) This is generally known as the TU (*transferable utility*) case.

If the n-person game is zero sum (the sum of payoffs to all players is zero) or at least constant sum, then the game between S and $N - S$ can be solved as in Section Two-Person Zero-Sum Games, with S as maximizer and $N - S$ as minimizer. Let $v(S)$ be the value of this game.

If the n-person game is not constant sum, then the two-party game will be a bimatrix game as in Examples 5 and 6. In this case the situation is not quite as clear as before; nevertheless, we will define $v(S)$ as the largest amount (of utility) which S can guarantee for its members *no matter what* $N - S$ does.

We call $v(S)$ the *worth* of coalition S. The function which assigns to each subset S of N its worth $v(S)$ is the *characteristic function* of the game.

Example 9

In a game with three players, there is a trunk full of precious objects, valued at 1000 units. The trunk is too heavy for one person to lift, but any two of the three players can lift it together, and they will then be in possession of the trunk.

In this case, we have $N = \{1, 2, 3\}$, and

$$\begin{aligned} v(\{i\}) &= 0 \quad \text{for } i = 1, 2, \text{ or } 3 \\ v(S) &= 1000 \quad \text{for any } S \text{ with two or three players} \end{aligned}$$

By convention, we also have $v(\emptyset) = 0$ ($\emptyset$ being the empty set).

Example 10

A woman (player I) has a horse that she wishes to sell. She has no use for it. There are two possible buyers, players II and III. Player II values the horse at 1000 units, while player III values it at 500 units.

In this case, a single player can produce no utility. Neither can the coalition $\{2, 3\}$. On the other hand, the coalition $\{1, 2\}$ can produce a total of 1000 units of utility, to be divided among them as they wish. (If player I sells the horse to II, I's profit is then the price she receives for the horse, while II's profit is 1000 minus the price he pays. Their total profit is then 1000.) Similarly, $\{1, 3\}$ can produce 500 units of utility. This game has the characteristic function

$$\begin{aligned} v(\{i\}) &= 0 \quad \text{for } i = 1, 2, \text{ or } 3 \\ v(\{1,2\}) &= 1000 \\ v(\{1,3\}) &= 500 \\ v(\{2,3\}) &= 0 \\ v(\{1,2,3\}) &= 1000 \end{aligned}$$

Given the characteristic function of the game, we look for a way to distribute the amount $v(N)$ which is the total utility available to the set of n players. Assuming that no player will accept less than what he can guarantee in the worst of cases, we define an *imputation* as a vector **x** with n components such that

$$\begin{aligned} x_i &\geq v(\{i\}) \quad \text{for all } i \in N \\ \sum_{i \in N} x_i &= v(N) \end{aligned}$$

Thus, imputations are possible payoff vectors – allocations to the n players of the total amount $v(N)$.

In Examples 9 and 10, notice that the imputation set in each case is the set of all vectors with three nonnegative components adding to 1000. In this, the games are similar, but as we shall see, they are quite dissimilar in other ways.

The Core

Given a game in characteristic function form, **v**, we know its imputations. We still require some way to determine which imputations are in some way 'better' or 'more stable' than

others. We base this on *domination*. An imputation **x** dominates another, **y**, if there is some coalition S such that (1) all members of S prefer **x** to **y**, and (2) S is strong enough to obtain **x**. Mathematically this means that $x_i > y_i$ for all $i \in S$, and $\sum_{i \in S} x_i \leq v(S)$. Then, the *core* of a game is the set of all undominated imputations.

In Example 9, the core is empty. For, let $\mathbf{y} = (y_1, y_2, y_3)$ be an imputation. The three components of **y** add to 1000, and thus at least one of them is positive. Assume that $y_1 > 0$. Then $\mathbf{x} = (0, y_2 + y_1/2, y_3 + y_1/2)$ dominates **y** (with $S = \{2, 3\}$). Similarly, all imputations are dominated, i.e., the core is empty.

In Example 10, the core is nonempty; it consists of all imputations of the form $(x_1, 1000 - x_1, 0)$, where $500 \leq x_1 \leq 1000$. This says that player I will sell the horse to II; the price cannot be more than 1000 since the horse is only worth 1000 units to II. On the other hand, the price must be at least 500 units as, below 500, player III will bid so as to raise the price.

The Shapley Value

While the core is an intuitively appealing solution concept for n-person games, we note that in many cases it will be empty. It also fails to take certain possibilities into account. In Example 10, e.g., the two buyers might collude so as to bring the price of the horse below 500 units: player III realizes he will be outbid anyway, so he agrees to stay out of the bidding for a price (a side payment from II), and so an outcome such as (300, 600, 100), although not in the core, is not out of the question. For these reasons, theorists have looked at alternative solution concepts. Perhaps the best known one is the *value*, or *power index*, due to L.S. Shapley.

Given an n-person game **v**, Shapley looks for an outcome $\mathbf{\Phi[v]}$ – a vector with n components – which says what each player might reasonably expect to obtain in the game. His approach is axiomatic, based on the idea that two games (with the same players) can be added to give another game. He then gives four axioms that the value rule $\mathbf{\Phi}$ should satisfy: efficiency (S1), dummy exclusion (S2), symmetry (S3), and additivity (S4).

Of these, S1 says that all players together should receive the amount $v(N)$. S2 says that a player who contributes nothing – good or bad – to any coalition will receive nothing. S3 says in effect that if $v(S)$ depends only on the number of players in S, then all players in the game should receive the same amount. Finally, S4 says that the value $\mathbf{\Phi[v + w]}$ of the sum of two games is equal to the sum $\mathbf{\Phi[v]} + \mathbf{\Phi[w]}$ of the values of the two games.

We then obtain the following theorem:

Theorem 5

There is a unique value rule, defined over the space of all n-person games, satisfying the axioms S1–S4. This rule $\mathbf{\Phi}$ gives to player i in game **v** the amount

$$\mathbf{\Phi}_i[\mathbf{v}] = \sum \frac{(s-1)!(n-s)!}{n!}[v(S) - v(S - \{i\})]$$

where the summation is taken over all coalitions S with $i \in S$, and s is the number of elements in set S.

As may be seen, the value assigns to player i a weighted average of her *marginal contributions* $v(S) - v(S - \{i\})$ to the several coalitions she may join (cf the usual economic idea of paying factors of production according to their marginal product).

In Example 9, it is no great surprise that the value is (333.3, 333.3, 333.3). In Example 10, the value is (583.3, 333.3, 83.3). Note that player I – as the only seller, with two buyers – is in a position to obtain most of the profits. Note, however, that player III gets something – he is not quite so helpless as the core analysis above would have us believe.

Other Solution Concepts

The core represents a very strong type of stability, which need not exist; the Shapley value gives us a kind of expectation which does not take into account prior relations among the players. Thus, other solution concepts have been proposed, some looking for a weaker type of stability, and others perhaps looking for the outcome of a single play, or taking prior agreements among the players into account. We mention only a few of these.

Von Neumann and Morgenstern developed *stable sets* which represent 'standards of behavior.' A set V of imputations is stable if (a) no imputation in V dominates another, and (b) every imputation outside V is dominated by at least one in V.

R.J. Aumann and M.B. Maschler developed *bargaining sets*, based on the idea that, in a coalition, some players may *object* to a payoff if they feel that others in the coalition are receiving too much of the coalition's profits. The objected players may be able to show, by means of a *counterobjection*, that they can protect their share. A payoff vector is in the bargaining set if, for any objection, there is a counterobjection.

Other solution concepts include the *kernel*, due to M.B. Maschler and M. Davis, and the *nucleolus*, due to D. Schmeidler. Modifications of the Shapley value, using information about some players' relationships to others, have been suggested. Chief among these are one by R. Myerson and another by G. Owen.

Modifications of the Game Model

Games with Nontransferable Utility

As mentioned in Section The Characteristic Function, von Neumann and Morgenstern's theory is based on the assumption that utility is freely transferable (at a one-for-one rate) between members of a coalition. In real life this may not be possible, either because there is no perfect 'money' (to be identified with utility) or because rules (e.g., antitrust laws) forbid it. Theorists have therefore developed a model for games without side payments (the NTU case) (one in which utility is not freely transferable). In these games, $v(S)$, rather than a single number, is a set in s-dimensional space – a generalization of the two-dimensional sets discussed in Section Nash's Bargaining Model. It is possible to define imputations, dominations, and the core for these games. Attempts have been made to generalize other concepts – mainly the value and the bargaining sets – but no generalization seems as satisfactory as the original (TU case) (one in which utility can be freely transferred among coalition partners) concepts.

Games with Incomplete Information

Game theory usually assumes that the players have *complete information* (a situation in which a player knows all the laws of the game she is playing) as to the game they are playing – e.g., they know the strategies available, the probabilities at chance moves, and the payoff functions. In practice this need not be so. Thus theorists (J.C. Harsanyi, R.J. Aumann, and M.B. Maschler, among them) have studied situations in which the players have subjective probabilities as to the games they are playing. Aumann and Maschler have studied the problem faced by a player who wishes to use private information but fears that its use may reveal this information to an opponent, and the dual problem faced by a player who wishes to elicit information from an opponent's moves.

Game Theory: Noncooperative Games

Eric van Damme, Tilburg University, Tilburg, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

We describe noncooperative game models and discuss game theoretic solution concepts. Some applications are also noted. Conventional theory focuses on the question 'how will rational players play?', and has the Nash equilibrium at its core. We discuss this concept and its interpretations, as well as refinements (perfect and stable equilibria) and relaxations (rationalizability and correlated equilibria). Motivated by experiments that show systematic theory violations, behavioral game theory aims to integrate insights from psychology to get better answers to the question 'how do humans play?'. We provide an overview of the observed regularities and briefly sketch (beginnings of) theories of boundedly rational play.

Introduction

Games are mathematical models of interactive decision situations, i.e., situations in which multiple decision makers, each one with its own objectives, jointly determine the outcome. Game theory aims to predict what players will do in such situations and what outcomes will result. The theory has been applied in economics, other social sciences, biology and computer science, among others. Aumann (1987) presents an overview of how the field developed in the twentieth century. The 3-volume *Handbook of Game Theory with Economic Applications* (Aumann and Hart, 1992/1994/2002) provides a fairly complete overview of rationalistic game theory in almost 2400 pages. Excellent textbooks at the graduate level are Myerson (1991) and Osborne and Rubinstein (1994). For more information and detailed references, the reader is advised to consult any of these sources. Behavioral game theory is more recent, less established and developing more quickly; Camerer (2003) provides a good starting point for this branch.

The Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel has been awarded to game theorists four times. In 1994, John Harsanyi, John Nash and Reinhard Selten shared the Prize for developing equilibrium theory in noncooperative games; in 2005 Robert Aumann and Thomas Schelling shared it for enhancing our understanding of conflict and cooperation by mean of game theoretic analysis; in 2007 Leonid Hurwicz, Eric Maskin, and Roger Myerson were praised for developing the theory of mechanism design, while in 2012 Alvin Roth and Lloyd Shapley received the Prize for the theory of stable allocations and the practice of market design. Researchers from closely related fields were honored in 1996 (James Mirrlees and William Vickrey; incentives under asymmetric information), in 2002 (Daniel Kahneman, Vernon L. Smith; behavioral economics and experimental economics), and in 2009 (Elinor Ostrom (who shared the Prize with Oliver Williamson); institutional economics). Excellent information on the contributions of the Prize winners is available on the official web site of the Nobel Prize, http://www.nobelprize.org/nobel_prizes/economics/laureates/index.html. In 2014, the Prize was awarded to Jean Tirole, who also made important contributions to noncooperative game theory, among others together with Drew Fudenberg and Eric Maskin.

The game theory literature distinguishes two main classes of models: cooperative games and noncooperative games. The terminology, which suggests that in one case the players cooperate and in the other they do not, is misleading. The difference is not in what players want, but rather in what they are allowed to do. Traditional game theory assumes that players are rational and strive to maximize their utility; in this respect, there is no difference between the two models. In noncooperative theory, however, it is assumed that the model is complete and that the players are bound by its rules. In particular, contracts or commitments are binding only if the formal rules explicitly allow this. By contrast, in cooperative theory, players are free to negotiate, form coalitions and possibly make side payments, and are assumed to have access to a costless external mechanism that enforces agreements. Noncooperative theory assumes such an external mechanism is absent, hence, focuses on self-enforcing agreements.

The distinction was coined by John Nash in his Ph.D. thesis (Nash, 1950), which also introduced the fundamental solution concept for noncooperative games (the Nash equilibrium concept). In the path-breaking Von Neumann and Morgenstern (1944), the founders of game theory had developed two distinct theories: one for two-person games in which the players have strictly opposite interests (two-person zero-sum games) and another for n-person games in which the players can form coalitions and make side payments. They had argued that, as soon as there are more than two players, choosing an ally and forming a coalition becomes crucial, with side payments being key in stabilizing cooperation; hence, that two-person zero-sum games, in which such possibilities are irrelevant, are the exception. Consequently, they assumed that a mechanism enforcing coalitions and contracts was available and focused on cooperative theory. Nash extended Von Neumann and Morgenstern's two-person zero-sum theory and developed the general noncooperative theory. In this theory, each player acts independently, without collaborating with any of the others, however, by making full use of all the possibilities for cooperation that the game allows.

A model should be rich enough to allow for the relevant possibilities, but also simple enough to allow in-depth analysis and yield insight. Nash argued that noncooperative models are more fundamental, as it should always be possible to model coalition negotiations as formal moves in a noncooperative game. Although correct, the resulting model may be too complicated and the attention for details may blur the general picture, hence, each type of model has its advantages. Possibilities for cooperation can be modeled either as part of the game, or as part of the solution concept. In this contribution,

we limit ourselves to the former approach. As we will see, there exist various deep links between the two approaches. Cooperative game theory is surveyed in William Thomson's contribution to this Encyclopedia.

The remainder of the material is structured as follows. We first describe the two main classes of noncooperative models (the extensive form and the strategic (or normal) form), and the concept of strategy that allows the reduction of one model to the other. Next, we turn to solution concepts that are based on the assumption that players are perfectly rational and have full understanding of the game. We discuss Nash equilibrium, some of its drawbacks, as well as extensions (correlated equilibria) and refinements of it, such as perfect and stable equilibria. The experimental literature has shown that human players may deviate from perfect rationality in systematic ways; hence, we next discuss recent results from the behavioral game theory literature, which aims to construct models of thinking and learning that are descriptively more accurate. We close by briefly discussing some applications, including the link between cooperative and noncooperative theory.

Noncooperative Game Models

An 'extensive game' is a very detailed model of a conflict situation; it specifies which players are involved and how the game evolves over time: which player moves when, what information does the player then have, what can he do, what are the possible consequences of his actions, and how do the players evaluate the outcomes? Von Neumann and Morgenstern (1944) already provided a set-theoretic description of this model, but Kuhn (1953) provided a graph theoretic formulation that is easier to work with and that has become the standard.

A special case is a game with 'perfect information,' in which the moves are sequential and each player, whenever he has to move, is fully informed about everything that has happened before. Chess is a game with perfect information. **Figure 1** gives a very simple example: player 1 (P_1) moves first and chooses between terminating the game, O, with payoff 1 to P_1 and X to P_2 or giving the move to P_2(action I), who then determines whether each player gets 0, or whether P_1 gets 2, with P_2 getting Y. We will return to this game below. Most of the literature has restricted attention to games with 'perfect recall' in which a player never forgets what he knew or what he has done before. Bridge, when modeled as a two-player game, has imperfect recall: if EW is the defending team, then W does not know (recall) the cards of E.

Figure 1 $X > Y > 0$

By means of the concept of strategy, already introduced in early work of John von Neumann, an extensive form game can be reduced to its strategic form. A 'strategy' for a player is a full plan of action for how to play the game, i.e., it specifies a unique action for each decision point of this player and each piece of information that this player might then have. Denote by N the set of players in the game and by S_i the set of all strategies for player $i \in N$. Assume that players evaluate outcomes by Von Neumann Morgenstern utility functions and let u_i be the utility function of player i. An n-tuple of strategies $s = (s_1, \ldots, s_n)$, one for each player, determines a probability distribution over the outcomes and, hence, implies a unique expected utility $u_i(s)$ for each player. Von Neumann argued that the 'strategic form' of the game, the tuple $<N, S_1, \ldots, S_n, u_1, \ldots, u_n>$ specifying players, strategies and payoffs, contains all the information that is needed for rational players to determine what to do. Consequently, it would suffice to develop theory for 'strategic games.' The literature has debated whether the details of the extensive form are indeed irrelevant (see Section Rationality and Equilibrium). **Table 1** gives the strategic form of the game from **Figure 1**: the rows are the strategies of P_1, the columns the strategies of P_2, and in each cell, the first number is the payoff (i.e., the utility) to P_1 and the second the payoff to P_2; a convention that will be followed throughout. Note that in a strategic game each player only moves once, with players choosing strategies simultaneously.

The interpretation of a 'strategic game' $<N, S, u>$ is that the data of the game are common knowledge: all players are fully informed who the players are, what strategies each of them has available and how all players evaluate the possible outcomes. Harsanyi (1968) showed how incomplete information can be incorporated into the model. In Harsanyi's model, the game starts with a chance move that distributes private information to each player. It is then common knowledge what pieces of information each player might have and with what probabilities, but the exact piece of information (also called the player's type) is only known to the player himself. Formally, a 'Bayesian game' is a tuple $<N, T, S, p, u>$, where N is the set of players, $T=T_1 \times \cdots \times T_n$ is the type space, p is a probability distribution on T, and u is the vector of utility functions, where each player i's utility may generally depend on all types and all actions taken, $u_i = u_i(t, s)$.

In a Bayesian game, information is distributed asymmetrically: P_i is informed about his type t_i and can choose his action $s_i \in S_i$ on the basis of it; P_j only knows his own type t_j and on this basis forms beliefs $p(t_i, t_j)$ about what P_i might know and might do, $s_i(t_i)$. As an example of a Bayesian game, think of a sealed bid auction: each bidder knows what the auctioned object is worth to him, but has only imprecise information

Table 1 A strategic game

	L	R
O	1, X	1, X
I	0, 0	2, Y

about the value of others. Also *see* the article on Auctions. A special class of Bayesian games, 'signaling games,' has proved fertile for theory development. In such a game, there is only one player with private information, but this player moves first; he has to decide how much information to reveal, while his opponents have to figure out what information his action might be signaling (*see* the article Information, Economics of).

It should be noted that above we referred to common knowledge in a loose sense: all players knowing something is different from that being common knowledge. The latter also implies that all players know that all players know it, and that all players know that all players know that all players know it, etc; see Aumann (1976) for a formal definition. Rubinstein (1989) shows that games with almost common knowledge are very different than games with common knowledge.

In the above discussion, we restricted attention to pure strategies; however, there is also the possibility of randomization. In a strategic form game, a 'mixed strategy' of P_i is a probability distribution σ_i over this player's set of pure strategies S_i. (We will write $\Delta(S_i)$ for the set of all such probability distributions.) It can be interpreted either as an act of deliberate randomization of this player, or as an expression of the uncertainty that the other players face about what P_i is going to do. In the latter case, σ_i represents the common beliefs held by the opponents of P_i. (The assumption that they have the same beliefs makes sense if they have the same information; in a Bayesian game, σ_i are the *ex-ante* beliefs, before the own type is known.)

In an extensive game, one can distinguish two types of randomization. When using a mixed strategy, the player randomizes over his pure strategies before the game starts. If the player randomizes locally over his actions at each of his information sets, this is called a 'behavior strategy.' A mixed strategy always induces a behavior strategy, but the converse only holds in games with prefect recall (Kuhn, 1953); hence, in these games, the restriction to behavior strategies is without loss of generality. Bridge provides an illustration that, without perfect recall, one may be able to play better with mixed strategies: to play optimally, the defending team needs to perfectly coordinate the actions of its members without revealing too much information; this is possible in a mixed strategy, but not when the team members randomize independently.

Rationality and Equilibrium

Nash Equilibrium

The fundamental solution concept for noncooperative games was introduced by John Nash in his 1950 PhD thesis. The mathematical core of the thesis was published as Nash (1951), but the chapter 'Motivation and Interpretation,' was not published, which may have led to misunderstandings and may have delayed development of the field.

Let $G = <N, S, u>$ be an n-person strategic game. A 'Nash equilibrium' of G is a strategy combination of σ(either mixed or pure) with the property that each player i is playing a best response against the strategies played by the others, hence $u_i(\sigma) = \max_{\tau_i} u_i(\tau_i, \sigma_{-i})$ for all $i \in N$. In other words, as long as the others do not deviate from their equilibrium strategies, player i cannot improve his payoff by deviating from his equilibrium strategy. An equilibrium of an extensive game is defined similarly; it simply is an equilibrium of the associated strategic game. An equilibrium of a Bayesian game is frequently called a Bayesian Nash equilibrium: each player plays a best response against the strategies of the others, whatever his type might be.

Nash provided two justifications for his concept. The first interpretation is rationalistic; Nash equilibrium is an answer to the question: what would perfectly rational players do? If we assume that a theory of rational play produces a unique solution and if the players know the solution, then rational (payoff maximizing) players will conform to this solution only if it is a Nash equilibrium. Any other (single-valued) theory is self-defeating. While assuming rational players to know the solution and to make use of their knowledge seems fine, the assumptions of existence and uniqueness are crucial. In fact, as a game may have multiple Nash equilibria (see below), this rationalistic justification seems incomplete at best. How can a player predict what another player will do if there are multiple Nash equilibria? This question motivated a fruitful, long-term research project of two Nobel Prize winners, who ultimately showed that additional, but not undisputable, assumptions allow one to come up with an answer; Harsanyi and Selten (1988).

The second 'mass action interpretation' assumes the game to be repeated, with each time players being newly drawn from certain populations and with each player accumulating empirical information on the relative advantages of their own strategies as well as on how often the opponents play their strategies. If the frequencies with which the various pure strategies are used converge, then "the mixed strategies representing the average behavior in each of the populations form an equilibrium point" (Nash, 1950: p. 22). In other words, under certain assumptions, learning leads to Nash equilibrium. Note that for this second interpretation, uniqueness is irrelevant; the initial conditions may determine at which equilibrium the process ends up. A large literature has investigated various types of learning processes and under which conditions convergence to equilibrium is indeed obtained; see Fudenberg and Levine (1998, 2009) and Young (2004) for overviews.

A third interpretation originates in the biological literature; see Smith (1982). Strategies are assumed to be randomly matched against each other with the payoff $u_i(\sigma)$ representing the fitness (expected number of offspring) of strategy σ_i when the state of the system is σ. The fittest strategies grow fastest, hence, if the system converges, it must be to a Nash equilibrium. The literature has studied various evolutionary processes, among which the replicator equation; see Weibull (1995).

By using a fixed point theorem (such as Brouwer's or Kakutani's) one can show that any strategic game has a Nash equilibrium, provided one allows equilibria in mixed strategies. 'Matching pennies' (two players simultaneously choose H or T with P_1 winning both pennies if the choices match and P_2 winning otherwise), shows that not all games have equilibria in pure strategies: in this game each player has to randomize.

Mixed strategies and mixed strategy equilibria are frequently viewed as being problematic, as players do not have

strict incentives to play them: any pure strategy in the support of a mixed equilibrium strategy is a best response as well. Mixed strategies, however, can also be interpreted as beliefs. Harsanyi (1973) showed that mixed equilibria arise naturally as beliefs associated with pure equilibria of a Bayesian game in which the uncertainty that each player faces about the other players' payoffs is explicitly taken into account. If one allows for the payoffs to be slightly uncertain, but each player being perfectly informed about his own payoff, then we have a larger Bayesian game $G(\varepsilon)$ in which each player i can play a pure strategy as for each payoff realization a specific pure action is optimal. However, as i's opponents do not know i's payoff realization, they will be uncertain about what action P_i will actually play. Given an equilibrium σ of a generic strategic game G one can find an equilibrium $\sigma(\varepsilon)$ of the Bayesian game $G(\varepsilon)$ such that, in the limit, as the uncertainty vanishes, for each $i \in N$ the beliefs of i's opponents associated with $\sigma(\varepsilon)$ converge to σ_i.

As noted, Nash's noncooperative model is a generalization of Von Neumann and Morgenstern's two-person zero-sum game. Indeed, Nash's equilibrium concept is a generalization of their minimax solution. The founders of game theory asked the question what is the highest payoff that a player can guarantee himself and they defined a minimax strategy as one that guarantees this value. For two-person zero-sum games, σ is a Nash equilibrium if and only if, for each player i, σ_i is a minimax strategy. If games are not strictly competitive, however, the two concepts differ; best responding against a player that pursues his own interests is different from optimally defending yourself against somebody that plays against you.

Table 2 lists three well-known games. In the Prisoners' Dilemma (**Table 2(a)**), (D, D) is the unique Nash equilibrium. This shows that an equilibrium may be (Pareto) inefficient; another outcome is preferred by both players. That constraints on cooperation can hurt players is unsurprising; they no doubt would agree on (C, C), if they could sign binding contracts. 'Battle of the Sexes' (**Table 2(b)**, with $X = 0$) is a game with two pure equilibria, and a mixed strategy one yielding each player 5/6, hence, a game may have multiple equilibria. In stag hunt (**Table 2(c)**, with $0 < X < 4$), (S, S) and (R, R) are Pareto ranked equilibria. Although (R, R) yields higher payoffs for both players, S is a safer strategy: it guarantees the payoff X, while, if only one player chooses R, he ends up with 0. In this game, there is a conflict between risk dominance and payoff dominance: if $2 < X < 4$, then (S, S) risk dominates (R, R) (Harsanyi and Selten, 1988). The strategic game from **Table 1** (with $Y > 0$) shows that some Nash equilibria may be unstable. (O, L) is a Nash equilibrium, but, for P_2, R is always at least as good as L and sometimes it is strictly better; hence, R weakly dominates L. We conclude that Nash equilibria always exist, that there may be multiple (nonequivalent) equilibria, and that some equilibria may be unstable.

Table 2 Three strategic form games

(a) Prisoners' dilemma			*(b) Battle of the sexes*			*(c) Stag hunt*		
	C	*D*		*L*	*R*		*S*	*R*
C	3, 3	0, 4	U	5, 1	0, 0	S	*X*, *X*	*X*, 0
D	4, 0	1, 1	D	*X*, *X*	1, 5	R	0, *X*	4, 4

By means of a model similar to Harsanyi's, Carlsson and Van Damme (1993) have shown that common payoff uncertainty can eliminate equilibria, hence, can serve as an equilibrium selection device. Consider a game as in **Table 2(c)**. If $X < 0$, then S is a strictly dominated strategy; R is strictly dominated if $X > 4$, while for intermediate values, there are multiple equilibria. Carlsson and Van Damme consider the situation where X can take any real value, with players facing uncertainty, but each player receiving a reasonably accurate independent signal X_i about the true value of X before making his decision. They coined the term 'global game' for the resulting Bayesian game. If P_i receives a very large signal ($X_i \gg 4$), he can be reasonably sure that R is dominated, hence he will play S. Similarly, each player will choose R if his signal is very negative. It is natural to focus on simple (switching point) equilibria of the global game in which each P_i plays R if and only if $X_i < x^*$, for some x^*; indeed the authors show that under certain assumptions only such equilibria exist. In such a Bayesian equilibrium, a player must be indifferent when receiving the signal x^*. However, as each player believes that the events $X_1 > X_2$ and $X_1 < X_2$ are approximately equally likely, indifference can hold only if, $x^* = 2$. In the limit, as uncertainty vanishes, players, hence, coordinate on the risk dominant equilibrium of the stag hunt. For further discussion on global games, on the conditions under which these have unique limit equilibria, the relation with common knowledge, and their applications, the reader is referred to Morris and Shin (2003).

Rationalizability, Iterated Dominance and Correlated Equilibria

Nash equilibrium assumes that players optimize and have correct beliefs about their opponents. The concept of rationalizability (Bernheim, 1984; Pearce, 1984) keeps the first assumption, but relaxes the second. It can be obtained as outcome of an interactive process. In the first step, all beliefs are allowed and any player i can choose any best response to these. In the second step, for any $i \in N$, the beliefs of i's opponents are only allowed to put positive weight on strategies that are best responses for P_i and any player j is only allowed to play strategies that are best responses to profiles of the resulting beliefs. The 'rationalizable strategies' are those that survive iterative application of this procedure. In games with a unique rationalizable outcome, weaker rationality assumptions suffice to obtain the outcome.

The above procedure is related to (but not fully equivalent with) the iterative elimination of strictly dominated strategies, where a pure strategy r_i of player i is 'strictly dominated' if there exists a mixed strategy σ_i such that $u_i(r_i, s_{-i}) < u_i(\sigma_i, s_{-i})$ for all s_{-i}. The difference is related to the question of whether beliefs about different players can be correlated or not. This issue does not arise in two-person games, for which the two procedures are equivalent. Note that any Nash equilibrium is rationalizable, however, Nash equilibria may vanish if weakly dominated strategies are eliminated (a pure strategy r_i is 'weakly

dominated' if there exists s_{-i} satisfying the above inequalities for some s_{-i} and corresponding weak inequalities for all s_{-i}).

Aumann (1974) introduced the concept of correlated equilibrium that generalizes Nash's concept to games in which communication between the players is possible. It assumes that players can conduct joint lotteries (play correlated strategies), but cannot make binding agreements or side payments. As an introduction, consider the game from **Table 2(b)** with $X = 0$ ('Battle of the Sexes'). If players can communicate, they can decide to throw a coin together and to play (U, L) when the outcome is H and (D, R), when the outcome is T. This correlated strategy yields each player the payoff 3, which is a good compromise. Furthermore, the agreement is self-enforcing: whatever the outcome of the coin toss, one player has a strong incentive to abide by the agreement and to follow up on it, so that it is in the best interest of the other to do so as well. We have a correlated equilibrium: a correlated strategy in which no player has an incentive to deviate from.

It will be clear that any convex combination of Nash equilibria is a correlated equilibrium. However, we can do more. Consider again the game from **Table 2(b)**, but now with $4 < X < 5$ and consider the scenario in which the players instruct a trustworthy mediator to randomize equally among the three cells of the matrix that have positive payoffs. Furthermore, they instruct him that, for each outcome of the lottery, P_1 shall only be informed about which row resulted while P_2 shall only be informed about the column. Viewing this information as a recommendation of what to play, one notices that, if one player always follows the recommendation, it is in the interest of the other player to do so as well. For example, if U is recommended, P_1 knows that P_2 has been recommended (and will play) R, hence, U yields the highest payoff. Similarly, if D is recommended, P_1 knows that P_2 will play L or R, each with probability 1/2, hence, again following the recommendation is best. The entire scheme is self-enforcing, hence, a correlated equilibrium, but it is not a convex combination of Nash equilibria. Formally, a 'correlated equilibrium' is a correlated strategy $\sigma \in \Delta(S)$ such that, for each player i, if $\sigma_i(s_i) > 0$, then s_i is a best response against $\sigma_{-i}(s_{-i} \mid s_i)$; in words: any recommendation s_i that any P_i might receive is a best response given $i's$ beliefs after hearing s_i.

Equilibrium Refinements and Stable Equilibria

We now focus attention on games in extensive form. Zermelo (1913) already showed that, in theory, chess can be solved by a backward induction procedure: starting at the end of the game, one works backwards replacing each decision point with the outcome that is obtained if a local best reply is taken there. It is straightforward to extend this procedure to any game with perfect information. Note that this procedure assumes persistent rationality: whatever happened before, each player assumes that all players will act rationally from then on. This assumption seems appropriate, but it is noteworthy that Von Neumann and Morgenstern (1944) already criticized it.

In the game of **Figure 1**, backward induction produces the Nash equilibrium (I, R). There is, however, a second equilibrium, (O, L), that is not consistent with this procedure. In effect, in this second equilibrium, P_2 threatens to choose L and, if believed, P_1 chooses O, so that the threat does not have to be executed. The question is whether the threat to play L really is credible. What is at issue here is that the strategic form of the game seems to assume that a player can commit himself to a strategy. However, in a noncooperative game such commitments are impossible, hence, when faced with the *fait accompli* that P_1 has chosen I, the best P_2 can do is to choose R. Strategies should not just be optimal at the beginning of the game, but also from each decision point onwards; in a noncooperative setting, only backward induction equilibria make sense. When a player is rational, the possibility to reoptimize should not lead him to deviate from his original strategy.

Following Selten (1965), a large literature on 'equilibrium refinements' has studied the question of how to generally eliminate Nash equilibria that rely on 'incredible threats.' Three related but conceptually different strands of literature can be distinguished.

The first line groups concepts that aim to extend the backward induction procedure beyond games with perfect information. Selten (1965) proposed 'subgame perfect equilibria': equilibria that induce Nash equilibria in all subgames; a subgame being a part of the game tree that constitutes a game of itself. Kreps and Wilson (1982) strengthened this idea and introduced 'sequential equilibria.' Such an equilibrium consists of a strategy profile σ, together with a system of beliefs μ that for each player specifies a probability distribution over the nodes in each information set. Two conditions are required:

1. Sequential rationality: at each information set, the player's strategy is optimal against the strategies of the others given the beliefs.
2. Consistency: the system of beliefs should be compatible with the strategy profile.

Various formalizations of consistency have been proposed. The main advantage of this framework is that it provides a natural language to discuss 'reasonableness' of beliefs and of the associated equilibria, hence, sequential equilibria can be further refined by imposing additional conditions on the beliefs. For example, in signaling games, one can insist that, upon observing action a_i, uninformed players assign beliefs $\mu(t_i, a_i) = 0$ to those types t_i of the informed player for which a_i is dominated or equilibrium dominated (*see* the article on Alternative Schools of Economic Thought).

In the second strand of literature, it is assumed that players will, with a small probability, make mistakes and it is required that equilibria be robust against this possibility. Hence, perfect rationality is viewed as a limiting case of slightly imperfect rationality. The seminal paper in this strand is Selten (1975), which introduced the concept of 'perfect equilibrium,' based on the idea that all players make independent mistakes at each of their information sets. When players tremble, all decision nodes are reached with positive probability, so that an optimizing player is forced to choose a best response everywhere. Consequently, in the perturbed game there cannot be incredible threats. An equilibrium is said to be perfect if it can be obtained as limit of Nash equilibria of a sequence of perturbed games when the mistakes vanish. As Kreps and Wilson (1982) define their main consistency requirement in terms of mistakes, there is a clear

link between the two strands: any perfect equilibrium is sequential. The perfectness concept can be refined by imposing further conditions on the mistakes. For example, Roger Myerson's proper equilibrium insists that more costly mistakes occur with much lower frequency.

Sequential equilibria and perfect equilibria rely essentially on the extensive game structure. As a result, two extensive games with the same strategic form may have different sequential or perfect equilibria. Kohlberg and Mertens (1986) argued that such dependency is undesirable: fully rational players are not misled by presentation details that are strategically irrelevant. Hence, they argued in favor of a solution that satisfies invariance, i.e., which only depends on the strategic form. The game from **Figure 1** illustrates that the backward induction property may be uncovered in the strategic form: (I, R), the only strategy pair to survive backward induction in the extensive game, is also the only one surviving interactive elimination of weakly dominated strategies in the strategic form. Hence, we have two different rationality principles that produce the same outcome. More generally, a proper equilibrium of a strategic game induces a sequential equilibrium in any extensive form game with that strategic form. Hence, it seems possible that 'robust' equilibrium outcomes can be identified in the strategic form.

Kohlberg and Mertens (1986) initiated the axiomatic approach to equilibrium refinement: they postulate several properties that a rational solution should satisfy and investigate whether a solution satisfying these properties exists. Examples of such properties are: (1) invariance (already discussed above), (2) consistency with one-person decision theory (admissibility), (3) independence of strategies that are dominated or that are suboptimal responses against the solution, and (4) a solution should remain whenever a game is embedded in a larger one (the small worlds property). Kohlberg and Mertens (1986) proposed to strengthen perfectness by insisting not just on stability against one particular sequence of trembles, but against all small trembles. As typically a single equilibrium will not have this property, they suggested looking at minimal closed and connected sets of equilibria that are stable in this sense. This initial attempt did not satisfy all properties that they considered desirable, but Mertens (1989) next proposed a concept that indeed satisfies all of them. The definition of Mertens stability is highly technical, insisting on certain homology properties of the best reply correspondence. Govindan and Wilson (2008) defined the related concept of metastable equilibria that is somewhat weaker than Mertens stability, but satisfies the same decision-theoretic properties.

We thus conclude that the question 'how to exclude Nash equilibria that rely on incredible threats?' has led to highly technical questions about the best reply correspondence of the game. Exactly why such sophisticated techniques appear necessary to solve such an intuitive question is still imperfectly understood. Nevertheless, that stability suffices for that purpose can be shown with a simple example, which also illustrates the concept of forward induction. Consider the game in which P_1 first chooses whether to take up an outside option yielding him payoff 2 or to play Battle of the Sexes (the game from **Table 2(b)** with $X = 0$). Taking up the outside option is part of the perfect equilibrium (OD, R): if P_1 thinks that (D, R) will be played in the subgame, he is better off taking his option. However, this outcome does not seem reasonable: P_1 not choosing the outside option and then playing D is strictly dominated. Being requested to play, it seems that P_2 should, therefore, conclude that P_1 will play U and should respond with L. Hence, only the outcome (5, 1) seems reasonable. Indeed, this is the only stable equilibrium outcome.

This same outside option game may, however, illustrate that in case communication is possible (hence, when the basic solution concept is correlated equilibrium), we cannot insist on the solution to just depend on the strategic form. Exactly when the communication takes place may matter. If players can only communicate before the start of the game, P_1 can never be induced to play ID, hence, communication is immaterial and the outcome is (5, 1). On the other hand, if players can communicate after P_1 has thrown away his option, then players can randomize between (5, 1) and (1, 5), hence, P_1 can be induced to give up his option. Extensive form correlated equilibria are different from strategic form correlated equilibria, and for good reasons; see Myerson (1991; Chapter 6), where one can also find some remarks on how to refine correlated equilibria.

Behavioral Game Theory

Conventional game theory, with its focus on the question 'how will rational players play?' frequently makes sharp predictions about the outcome or about how this outcome changes with a change in the data (comparative statics), hence, studying the theory's empirical relevance appears quite natural. Testing with field data, however, has its limitations, and although there are exceptions, serious experimental investigation of the descriptive relevance of rationality-based theory only started in the 1980s (Kagel and Roth, 1995). The first wave of experimental studies established that standard theory sometimes (or frequently, depending on one's viewpoint) provides poor predictions of how humans play, and that there are systematic patterns in the deviations, which has then led to revised theories (or at least models) of play incorporating these regularities. In the last 25 years, emphasis has thus shifted to the question 'how do humans play non-cooperative games?' leading to a strong interaction between theory and empirical work.

This section provides a brief overview of the results that have been achieved in this rapidly developing field. We start by describing how human players deviate from conventional rationality. Three aspects can be distinguished: (1) motivation (what drives people; how do players evaluate outcomes?); (2) cognition (how do people reason; what thinking processes do they use when they are confronted with a new game?); and (3) adaptation (how do people learn when they play the same game repeatedly?). After having described empirical regularities, we briefly discuss novel theories relating to each of these aspects.

Bounds on Human Rationality

Humans have emotions, face cognitive limitations, and may be under (time) pressure; they process information differently, or may be motivated differently than standard theory assumes. Conventional theory is silent on the decision-making processes

that are used. It assumes that players only differ in preferences, not in cognitive abilities. Models of bounded rationality take into account limits on human knowledge, informational processing capacity and computational ability. Obviously, in some games, these limits are more important than in others.

When observed behavior differs from the game theoretic prediction, one can point to one of two main causes:

1. The game, as perceived by the players, is different from the one analyzed by the theorist.
2. The solution concept is not applicable in this situation.

Conventional game theory starts with the model and assumes that it is common knowledge among the players. Real life conflict situations are less structured and have to be interpreted; a model has to be constructed, and different players may perceive the situation differently. At first, one does not necessarily see all aspects of the problem, leading to superficial decision making. Nevertheless, this may already produce a satisfactory solution, not inviting further reflection. Selten (1998) notes that such superficiality may explain the framing effect (Tversky and Kahneman, 1981): the way the situation is presented may have an important influence on the outcome. The reasoning process anchors at aspects that deeper inspection might reveal to be irrelevant. Alternatively, framing may provide clues to the solution that conventional theory mistakenly neglects; Schelling (1960).

Traditional models assume that players are rational in the sense of Von Neumann and Morgenstern (expected utility) and Savage (subjective expected utility). Mostly, the assumption of players having a common prior is added. Following the path-breaking Kahneman and Tversky (1979), behavioral economics has shown that humans deviate from these assumptions and the resulting behavior in systematic ways: (1) utility depends not just on the final state (outcome), but on changes in the state; (2) the change is measured with respect to a reference point; (3) losses loom larger than gains (loss aversion); (4) individuals use decision weights that are different from probabilities, with small probabilities being overweighted and large ones underweighted; and (5) information is processed differently than Bayes' rule describes (*see* the article on Behavioral Economics for more details). Furthermore, while the rational choice model allows general preferences, in empirical work it is frequently assumed that players are selfish and care only about own materialistic payoffs. Many humans are motivated differently: altruism and reciprocity play a role, with (social) norms influencing behavior as well.

Equilibrium concepts assume that (1) players form beliefs about what others will do, (2) these beliefs are correct, and (3) players best respond to them. In equilibrium, players never are surprised. A game may be too complicated to find a best response, or players may be insufficiently motivated to find one. Equilibrium concepts are based on circular reasoning (fixed points; solutions to systems of equations), but, as stressed by Selten (1998), humans have a tendency to avoid circular concepts. The natural way of problem solving is by using step-by-step reasoning processes. The rationalistic interpretation of equilibrium assumes, but leaves unexplained how the beliefs of players that are confronted with a new game come to be correct, an assumption that is especially problematic in games with multiple equilibria. Finally, natural learning processes need not converge to (Nash) equilibrium, or the learning may be too slow to be practically relevant.

Although for certain classes of games, nonequilibrium concepts, such as rationalizability or iterated dominance, are sufficient to predict the outcome, these rely on an unlimited number of iterations; humans seem to do only a very small number of rounds of iterated strategic thinking. Related, humans find processes like backward induction to be unnatural and do not always use these.

Empirical Regularities

Bounded rationality (the rationality displayed by humans in decision-making situations), hence, differs significantly from perfect rationality. As a result, it is not surprising that experiments have revealed that outcomes observed when humans play games differ systematically from the standard game theory predictions; see Camerer (2003), Goeree and Holt (2001), and Selten (1998). The following are some observed empirical regularities:

1. Framing effects can be very important, even in simple zero-sum games.
2. The outcome may depend on aspects of the game that conventional theory considers to be irrelevant; in contrast, aspects that the theory considers relevant need not matter; for example, two games with the same unique mixed strategy equilibrium may be played differently.
3. Not only the ordering of the payoffs matters, but also payoff differences: strategies that are not best responses may be played and small payoff differences may be ignored altogether.
4. Frequently, players care about other aspects than own (material) payoffs.
5. In games played once, the observed outcome may differ from the unique rationalizable one; in strategic games, people only do a small number of rounds of iterated elimination.
6. In perfect information games, monitoring of the decision making process shows that players may not do backward induction; this procedure does not come naturally, but it can be taught.
7. When players gain experience with a game, they adjust behavior; players learn in different ways and with different speeds, which may depend on the game; learning processes may be very slow.

Players' Motivations

The ultimatum game (Güth et al., 1982), along with its variants, the dictator game and the trust game, has spawned a large literature on social preferences. In the ultimatum game, P_1 proposes how to divide an amount of money between him and P_2; if P_2 accepts, the proposal is implemented; otherwise, each player gets 0. If both players are selfish (care only about own material payoffs), P_1 offers (close to 0) to P_2, which the latter accepts. Experiments, however, show that most offers are close to 50/50 and that the responding player may reject

considerable amounts. The dictator game (the variant in which P_2 is forced to accept all proposals) allows to test whether the behavior of P_1 is driven by altruism or by the fear that low offers will be rejected. In the trust game, P_1 can first transfer all or part of the amount to P_2, with that amount, T, being multiplied by a known constant $K > 1$, and with P_2 subsequently deciding how much to transfer back. In this game, responding players display positive reciprocity: the larger the transfer received, the more is transferred back. In public goods games, we see negative reciprocity: players that do not contribute sufficiently to the public good are punished. All these games show considerable individual heterogeneity, while culture matters as well; Henrich et al. (2004).

While the experimental results do not refute game theoretic analysis as such, they suggest that great care is needed in modeling a situation as a game; the frequently made assumption of selfishness does not describe most situations very well. Player 2 may be motivated to get a reasonable share and he may prefer conflict to an outcome in which he gets much less than the proposer. The game of **Figure 1** is a kind of mini-ultimatum game: P_2 may reject if Y is too small. On the other hand, if $X \cong 0$ and $Y = 1$, P_2 might realize that P_1 is forced to divide asymmetrically; he may accept in this case, while he might possibly reject if X is large and $Y \cong 0$. Hence, not only the outcomes matter, but also the context in which these arise; consequentialism is violated. In the literature, a large variety of models has been proposed and tested to incorporate these aspects, including models of pure distributional preferences, as well as models in which intent or procedural aspects matter. Given heterogeneity, incomplete information about preferences is natural, and there are also models in which players care about what others think of them.

Sobel (2005) is a recent overview of the literature on interdependent preferences.

In many models that fit under this heading, just the players' payoff functions are changed by incorporating behavioral aspects, while the solution concept remains conventional. Geanakoplos et al. (1989), however, argued that emotions cannot be captured by assuming that payoffs just depend on players' actions. Players' emotions, which influence how outcomes are valued (payoffs), will also depend on their expectations and, hence, on what they learn in the game. For example, in **Figure 1**, if P_2 expects P_1 to choose O, then he may be disappointed when asked to move and, therefore, choose R, while a P_2 in that expected I may simply play L. Geanakoplos et al. (1989) introduce 'psychological games' as games in which payoffs depend both on what players do and on what they think and they define a 'psychological equilibrium' as a profile in which each player best responds and beliefs are correct. Rabin (1993) builds on this idea to construct a model that incorporates considerations of fairness. Starting from an ordinary game and players' expectations, he first applies a kindness function to modify the payoffs to take into account the emotions and construct a psychological game, to which then the concept of psychological equilibrium is applied. The resulting outcome is called a fairness equilibrium. In the game from **Figure 1**, both the outcome (1, X) and the outcome (2, Y) can be supported by fairness equilibria.

Modeling Players' Thinking Processes

The p-beauty contest game ($0 < p < 1$) illustrates the difference between individual human rationality and rationalizability. In this game, n players are asked to simultaneously pick an integer from $\{1, 2, \ldots, 100\}$, with the person whose number is closest to p times the average being the winner (ties broken randomly). The unique Nash equilibrium is for all to choose 1; in fact, if $p < 3/4$, only 1 is rationalizable. Experiments show that players that are new to the game exhibit distinct, bounded levels of reasoning. For example, for $p = 2/3$, games played with a large population of players, show spikes at numbers such as 50 (superficial thinking), 33 (the best response against 50), 22, 15, 10, etc. Obviously, not all players are perfectly rational, and in such situations, a fully rational player should not necessarily pick 0.

If one knows that other players are not that sophisticated and engage only in limited thinking, a natural idea is to try to figure out what naïve players might do and to estimate the distribution of 'levels of thinking' in the population, and to best respond against the resulting beliefs. For example, if one thinks that naïve, level-1 and level-2 players are equally likely, one believes the average chosen by the others to be 35 and chooses 23. Theories of cognitive hierarchy (Camerer, 2003) or level-k thinking have been developed, and have been brought to the data with reasonable success; see Crawford et al. (2013) for a recent overview.

Some insight has also been gained on the question of how 'naïve play' is obtained: players come to the laboratory with prior ideas and may seek for analogies with known situations, or may seek for clues, such as labels and focal points; Schelling (1960). It has also been shown that backward induction reasoning does not come natural; for example, eye tracking studies show that many players only look for a limited time, or not at all, at the parts of the game tree that come later; hence, there is a tendency for myopic decision making.

Learning

When players get more experience with a game, they will typically adjust their behavior. As already suggested in Nash (1950), learning may produce outcomes that are more in line with equilibrium predictions. For example, in repetitions of p-beauty contest games, smaller numbers are chosen over time. We already noted that there is a very large theoretical literature on learning. In broad terms, two types of learning models can be distinguished. In belief learning, players adjust their beliefs about what others will do and best respond to these. In reinforcement learning, a player's own strategies have certain 'attractions,' which determine the probability of playing them and which are adjusted through time. Camerer (2003) describes a hybrid model, experience-weighted attraction learning that has successfully been fitted to the data of several games. The data and model show that learning is much quicker in some games than in others, hence, that players come to certain games with rather strong, but not necessarily correct, beliefs. Of course, not all people learn in the same way and some people may learn quicker than others. Selten (1998) stresses that learning may involve a combination of adaptive and analytical approaches.

Players that view the situation as routine and use adaptive methods may fail to acquire an overview of the situation and, hence, may not be able to reach equilibrium; for that, a more analytical approach may be needed.

Conclusion

The allotted space only allows making just a few remarks on the applications of noncooperative game theory; the interested reader is suggested to consult the Handbook of Game Theory or to follow any of the leads given below.

One application is to cooperative game theory. The 'Folk Theorem' shows that when a game is repeated sufficiently often, players are sufficiently patient and obtain enough information about past play (and when some other technical conditions are satisfied), the set of subgame perfect equilibrium outcomes coincides with those of the static cooperative game. Hence, in a context of repeated interaction, contracts may not be necessary to achieve efficient outcomes. Work of Nobel Prize winner Elinor Ostrom on the exploitation of common property resources combines this theory with rich institutional data. Avner Greif's contribution to the Handbook surveys the related literature that employs game theory for economic history analysis.

Following Nash's (1950) suggestion, the literature has pursued the 'Nash program' and has shown that several cooperative solution concepts can be implemented noncooperatively, i.e., there exists a noncooperative game of which the (refined) equilibrium outcomes correspond to those predicted by the cooperative solution concept. For example, the Nash-bargaining solution can not only be implemented by means of the simultaneous bargaining game proposed already in Nash (1953), but also by a very natural alternating offers procedure proposed in Rubinstein (1982). In a similar vein, solution concepts such as the Shapley value, the kernel, and the nucleolus can be obtained by noncooperative procedures; we refer to Thomson's article in this Encyclopedia for details.

Within economics, the field of industrial organization has proved a fertile ground for application. Probably the most successful applications thus far have been to auctions or more generally market design; see the article on Auctions. Following the seminal work of Vickrey, auction theory first focused on the questions of how to bid in a single-item auction and what is the revenue maximizing mechanism for selling such item. In implementing spectrum policy, governments were, however, confronted with the question of how to sell multiple heterogeneous items, given certain objectives, such as market efficiency and raising sufficient government revenue. Research, in which game theorists interacted with experimental economists and Operations Researchers, has led to highly innovative auction designs, such as the simultaneous multiround auction and the combinatorial clock auction, which have subsequently been successfully implemented by various governments around the world.

By using both cooperative and noncooperative approaches, and by combining theory with experimental and empirical studies, Nobel Prize winner Alvin Roth and coworkers showed that stability is important for understanding the success of particular market institutions. Building on this insight, they successfully reengineered several existing institutions, such as those for matching organ donors with patients. Importantly, this work shows that economics can take into account ethical restrictions, such as the prohibition of side payments.

As seen above, game theory has provided a strong stimulus for experimental economics. No doubt, the further development of behavioral game theory will give a further boost to applications.

Abstract

This article summarizes theoretical and empirical developments and trends in the sociology of gangs. Definitional issues and the history of sociological interest in gangs are reviewed first, followed by discussion of major research findings concerning gangs and gang members. Attention then turns to continuity and change in youth and gang cultures and in their relationships with violence. We close with brief comments concerning the state of gang scholarship and future research needs.

Introduction

Beginning with Frederic Thrasher's classic, *The Gang: A Study of 1313 Gangs in Chicago* (1927), gangs have been a subject of continuous sociological scrutiny, law enforcement attention, and public interest. Although the term *gangs* has been applied to groups of adult criminals, especially those that control segments of organized and professional crime, the preponderance of scholarly attention has focused on youth. The ever-changing nature of gangs and disagreement among and between scholars and law enforcement agencies concerning what kinds of groups constitute youth gangs hampers growth of knowledge about gangs and gang control. Nevertheless, study of gangs provides opportunities for advancing knowledge of broader principles of human behavior at every level of explanation. Defining gangs broadly as groups of youth that are unsupervised by adults and self-determining with respect to membership criteria, group structure, and behavior, this article traces continuity and change in processes associated with gang formation and behavior.

Definitional Issues

The term *gang* is both a theoretical construct and an object of varying definitions in legal statutes, legal and social agency policy, and popular discourse. *Gang* and other terms (*mob*, *syndicate*, *outfit*, etc.) have been applied to many types of groups, including those associated with organized and professional crime and incarcerated felons. Scholarly attention, however, has focused primarily on youth gangs, although 'setting and style' are beginning to matter more as "age becomes less of a defining characteristic" of gangs (Klein, 1995: p. 21).

A major sticking point in the literature concerns the role of crime in defining gangs. While some scholars argue that gangs and crime must be defined and measured independently of one another in order to avoid tautology, others contend that the centrality of crime and violence in youth gangs is what most distinguishes them from other troublesome peer groups, such as tagger crews. Still others suggest compromising by focusing on the "tipping point beyond which we say, 'Aha – that sure sounds like a street gang to me'" (Klein, 1995: p. 30). Two major 'signposts,' Klein argues, are degree of commitment to a criminal orientation and self-recognition of gang status. In later writings, Klein articulates the Eurogang consensus nominal definition of street gangs, based on intense collaboration involving American and European gang scholars (see Klein, 2006): "A street gang (or a troublesome youth group corresponding to a street gang elsewhere) is any durable, street-oriented youth group whose own identity includes involvement in illegal activity."

With Cheryl Maxson, Klein has investigated the practical implications of differing official definitions of gang crime. In the United States, some jurisdictions require evidence of gang motivation before a crime is legally defined as 'gang-related,' whereas other jurisdictions consider a gang-related crime to have occurred simply if the offender, victim, and/or both are suspected or known gang members. Analyzing data from Los Angeles police and sheriff departments, Maxson and Klein (1990) showed that, while estimates of the characteristics of homicide incidents (e.g., demographics, setting, use of firearms, offender-victim relationship, retaliatory motive, etc.) are robust to definitional variations, estimates of the prevalence of gang-related homicide are substantially higher under the gang-member definition than the more restricted gang-motivation definition. Such definitional ambiguity leaves open the possibility of exploitation by law enforcement agencies and officials primarily for financial, political, and other organizational gain, as observed in a study of a 'moral panic' surrounding gangs in Nevada in the late 1980s (McCorkle and Miethe, 1998).

Historical Background of Scholarly Research on Gangs

Frederic Thrasher's (1927) *The Gang* was the first attempt to survey the extent of youth gang activity in a major city, and perhaps the first in any jurisdiction. The project involved census and court records, personal observations, and personal documents collected from gang boys and from persons who had observed gangs in various contexts. Studies by Clifford Shaw and his collaborators provided even more information about the collective nature of youthful delinquency, consistently demonstrating that most boys who were brought before the juvenile court committed their delinquent acts in

the company of others. Case studies documented patterns of friendship, the association of younger with older offenders, and the influence of organized crime and other forms of adult criminality in communities with high rates of juvenile delinquency (Shaw, 1930; Shaw et al., 1929; Shaw and McKay, 1931, 1969[1942]; Shaw and Moore, 1931).

Ecological studies located delinquency in space and in relation to urban development, documenting economic and institutional contexts within which urban lives were lived and identifying forces that shaped the ability of communities to aid in the socialization of children and exercise control over their misbehavior. Theoretical insights from these studies continue to be important in thinking about youth crime. Foreshadowing 'labeling theory,' for example, Shaw's Jack-Roller – reflecting on his confinement in a reformatory – noted that he was no longer "just a mischievous lad, a poor city waif, a petty thief, a habitual runaway," but "a criminal" (Shaw, 1930: p. 103). Conversely, both Shaw and Thrasher noted that incarceration and criminal notoriety often had positive value among gang members, as it does today: "… residents in the vicinity south of the stock yards were startled one morning by a number of placards bearing the inscription 'The Murderers, 10,000 Strong, 48th and Ada.' In this way attention was attracted to a gang of thirty Polish boys, who hang out in a district known as the Bush" (Thrasher, 1927: pp. 62–63).

Thrasher's Murderers were involved in a good deal of criminal activity, but their primary pastimes "were loafing, smoking, chewing, crap-shooting, card-playing, pool, and bowling." Their "rudeness and thievery" were "an awful nuisance" to local shop keepers and neighbors (Thrasher, 1927: pp. 62–63). The arcane language notwithstanding, these excerpts highlight patterns similar to those observed among contemporary and earlier gangs involving 'hanging out' and episodic minor, as well as more serious, criminal behavior (Decker and Van Winkle, 1996; see Klein, 1995).

Ironically, gang research and subsequent ethnographic community studies (Suttles, 1968; Whyte, 1943) challenged the major theoretical legacy of ecological research in the city. Social disorganization theory attributed high rates of crime and delinquency to the lack of effective social organization and institutions in communities characterized by poverty, population heterogeneity, and turnover – just the sort of communities in which gangs were located. Yet, later studies documented highly organized groups and institutions in communities with high rates of crime and delinquency (Suttles, 1968; Whyte, 1943; see also Patillo, 2007).

Contemporary community research takes into account networks of interpersonal relationships and density of organizations, institutional domains, and leadership connections within and among neighborhoods (Bursik, 2002). Sampson and colleagues (1999; Sampson, 2012) combine these intra- and inter-neighborhood and community processes using the concept of 'collective efficacy,' that is, intergenerational closure linking adults and children, reciprocal local interfamily and interaction among adults with respect to children, and expectations that community residents will share child-control responsibilities. Collective efficacy is associated with the ability of local communities to exert effective control over violent and other forms of criminal behavior. Though not as well established empirically, so, too, are cohesive leadership and organizational relationships within the institutional domains that characterize the city.

Midway between Thrasher's classic work and the turn of the century, his book was abridged and reissued. Social changes had vastly altered the gang landscape, and gang research, heretofore largely descriptive, was changing in response to seminal theoretical proposals by Albert Cohen (1955), Richard Cloward and Lloyd Ohlin (1960), and Walter Miller (1958). Competing explanations for the origins of the delinquent subculture (Cohen), variations in delinquent subcultures (Cloward and Ohlin), and the role of lower-class culture in producing gang delinquency (Miller) stimulated empirical research and subsequent theorizing about the nature and behavioral effect of 'group processes,' especially 'status management' among gang leaders (Short and Strodtbeck, 1965). Controversy also erupted over the role of group cohesiveness in gang violence and the value of aggressive group programing by 'detached' community outreach workers (Jansyn, 1966; Klein, 1969, 1971).

By the last decade of the twentieth century, events that could hardly have been anticipated by earlier researchers had overtaken both theory and research. Whereas mid-century theories had outstripped available data, modest theoretical advances, and related empirical research were overwhelmed by the rapid proliferation of gangs in the United States and their spread to many other countries (Klein, 1995; Klein et al., 2001). In the United States, sophisticated firearms became more readily available to young people, often turning what previously had been 'non-zero-sum' contests between gangs into lethal confrontations (Anderson, 1999; Short and Strodtbeck, 1965). Weakened conventional economic, political, and family institutions lost legitimacy, contributing to rising crime rates (LaFree, 1998); and technological revolutions in the automotive industry, electronic communication, and entertainment media altered youth and gang cultures, aided by the institutionalization of some gangs, and created heretofore unknown problems for institutions of social control (Hagedorn, 2007, 2008; Moore, 1991; Vigil, 1988).

Change and Continuity

It is possible, nevertheless, to note both continuity and change in what is known about gangs, gang members, and the collective forms of delinquent and criminal behavior engaged in by young people (Short and Hughes, 2006):

1. Youth gangs are more prevalent in many countries than previously. Law enforcement agencies in all large US cities (over 250 000) report the presence of youth gangs, as do many suburban counties, small cities, and rural counties (including "Indian Country"), where gang prevalence is quite recent (Howell, 2012). European and UK researchers have identified variations in youth gang organization and behavior, some of them patterned after US gangs (Decker and Weerman, 2005).
2. Gangs in many parts of the world are comprised predominantly of youth who are marginalized in mainstream society as a result of race, ethnicity (including religion), or economic status (Hagedorn, 2007, 2008; Vigil, 1988). In the United States, these are predominantly African American and Hispanic, with increasing numbers of new Asian

immigrant children and children of immigrant parents. In Continental Europe and the United Kingdom, they tend to be the children of refugees from other countries or migrant workers. Gangs comprised of majority population youth, nearly always white, sometimes form in opposition to these marginalized groups, thus becoming marginalized themselves. Historically, however, white gangs formed first, followed by defensive black and Hispanic gangs (Howell, 2012).

3. Youth gangs are comprised overwhelmingly of young males, and the experience of females who associate with male-dominated gangs, or in all-female gangs, is quite different from the gang experience of males (Miller, 2008; Chesney-Lind and Hagedorn, 1999). Victimization, by male gang and family members, is a prominent theme in studies of female gang members. However, the specific experiences of female gang members appear to be conditioned by the structure and internal dynamics of their gangs, including group sex composition (Peterson et al., 2006).
4. The distribution and patterning of collective youth crime reflect the ecology of the places where they are located. In the United States and many other cities around the world, these are inner-city areas, much as they were in Thrasher's day. Where public housing projects are located outside central cities, gangs of loosely structured, ethnically mixed groups often 'commute' to areas where they engage in carousing, 'smash-and-grab' hits on stores, rolling drunks, robberies, and other problem behaviors.
5. Large aggregations of gang 'nations' emerged in a few large US cities, most notably Chicago and Los Angeles, during the 1960s and subsequent decades. Local gangs – wherever they are found – are primarily 'home grown,' but the influence of gang nations is widespread through mimicry, migration (sometimes forced by deportation) of gang members, and social media contacts. As in the past, many (probably most) gangs begin as nondelinquent friendship groups, 'hanging' groups, or groups formed around institutional (schools, youth serving agencies) nondelinquent activities, such as sports, singing, dancing, and so forth (see, e.g., Schwendinger and Schwendinger, 1985; Sullivan, 1989; Schwartz, 1987; Short, 1997). Although gangs vary along a number of dimensions, such as size, age range, and duration (Klein and Maxson, 2006), the primary distinguishing characteristic of all youth gangs is that they are self-determining with respect to membership criteria. Moreover, contrary to popular myths and depictions, most gangs are only loosely organized and incapable of sophisticated legitimate or illegitimate operations (see Coughlin and Venkatesh, 2003).
6. Studies suggest that unsupervised youth groups become violent, and otherwise delinquent, as a result of one or more of the following processes:
   a. escalation of the natural rough-and-tumble punching and wrestling that occurs among most male groups, and the association of status with fighting prowess;
   b. competition with rival groups involving status-enhancing activities, including retaliation, or economic motivations;
   c. conflicts based on racial/ethnic differences;
   d. definitions of groups as gangs, by others (including law enforcement personnel), and behavior toward them that reinforces a violent group identity;
   e. group processes that create or reinforce group cohesion based on violent or other delinquent behavior.
7. Due to rising rates of incarceration throughout much of the latter part of the century, the line between prison and street gangs has begun to blur, "as gang members are released into the community and as particular street gangs, such as the Bloods and the Crips, grow to be part of prison life when street members enter the correctional system" (McGloin, 2005: p. 608).

Street gangs are diverse in behavior, organization, continuity across generations, and in their relationships with other gangs and their communities. They change as members age and move into adulthood. The age range of many gangs has expanded in many countries, however, in response to the lack of attractive legitimate jobs. This change often is accompanied by increased violence, as gang members have turned to selling drugs and other illegal activities in order to support themselves, often with family approval and/or assistance (see Fagan, 1996; Fagan and Wilkinson, 1998; Hagedorn, 2007, 2008; Spergel, 2007). Violence and other delinquent activities occur frequently in 'staging' areas in which young people gather with friends and others in order to escape adult supervision (Anderson, 1999; Schwartz, 1987; see also Tita and Ridgeway, 2007).

Diversity and change among street gangs tend to blur distinctions between them and a variety of types of youth and young adult collectivities, including 'skinheads' and perhaps even perpetrators of mass shootings that have occurred on school properties (Moore et al., 2003). Although differing among themselves, these groups (and occasional isolated individuals) have in common their hatred of 'outsiders,' based on racial, ethnic, local status, or other exclusionary criteria, similar to crowds that gather to attack community outsiders, usually members of minority groups.

Drug and other 'working' or 'specialty' gangs are organized primarily around revenue-producing activities, such as drug selling, stealing, fencing stolen goods – all activities requiring greater organizational skills and structure than is characteristic of traditional street gangs. Also unlike street gangs, 'bikers,' 'punkers,' and sports fanatics and 'hooligans' are organized around specialized interests. Except for the latter (most of whom appear to be disadvantaged socially, rather than economically), these groups are comprised primarily of youth who have been marginalized by minority ethnic and/or economic status and who have poor prospects for integration or social mobility within dominant majority societies. The excessive behavior of bikers and sports hooligans also appears to be motivated in some measure by resentment of minorities.

Youth Culture

Virtually all youth are heavily influenced by the development, rapid growth, and diffusion of youth culture. Peddled by media advertising, and augmented by large social and economic forces that fail to provide meaningful roles for young people but cater to their distinctive fads, appetites, and currency, youth culture and gang culture together underlie the excesses of consumption and violence perpetrated by gangs.

Youth culture developed rapidly during the 1960s, especially in the United States. Young people born during the baby boom following World War II shared in the general level of affluence in the country, thereby creating a youth market with great economic power. Moreover, the period of education prior to entering the labor market was extended; increasing numbers of women joined the workforce, further separating mothers from youth in the home and in the neighborhood; adults worked increasingly in large organizations away from young people; and the mass media greatly expanded and focused their attention on the youth market (see Coleman et al., 1974: pp. 114–119). These changes accelerated as the century wore on, expanding their influence throughout the world.

Field researchers document the pernicious seductions of media-advertised products among less-affluent young people, leading often to thefts and assaults. Anderson (1999) describes the "zero-sum quality" that pervades the "code of the streets," in the search for respect – often associated with trivial items, such as shoes and jackets – among young African American men in the ghetto. Sullivan identifies "mutually valorizing cultural symbols" (clothing, drugs, alcohol, and recreational artifacts and activities, including graffiti and tattoos) that cut across racial and ethnic boundaries, often resulting in invidious comparison, confrontation, theft, and assault (Sullivan, 1989: pp. 248–249).

Adolescence is a period of especially intense identity formation, intense relationships, and shared feelings of friendship, acceptance, and respect. Conversely, feelings of rejection and disrespect also are especially intense and often the basis for group and subcultural formation. Observers of youth groups everywhere note that status differences within and between them are extremely variable and highly refined. Status criteria within a group, or between one group and another, may be based on race or ethnicity, relative economic affluence, skills in valued activities, public appearance, school performance or, perhaps most importantly, lifestyle differences. These bases of stratification typically also become criteria of inclusiveness and exclusiveness, which in turn create opportunities for both friendship and rejection.

Next to families, schools are perhaps the most important contexts for adolescent friendship, achievement, and recognition. Because of this, school contexts (including the journey to and from schools) are the settings for much adolescent behavior, including gang activities. On occasion, they also have been the setting for the most extreme forms of violence, including mass killings by students or others alienated from their fellows or from mainstream institutions in general. Although the specific causes of such extreme alienation are complex, it appears that schools have been targeted precisely because of their importance in the lives of adolescents, as symbols of rejection by both peers and an adult world that seems far removed from adolescent concerns. The ready availability of guns at times transforms normal adolescent turmoil and conflict into deadly confrontation (Moore et al., 2003).

More than ever before in history, young people, targeted for commercial exploitation and isolated from mainstream adult roles and institutions, confront economic conditions beyond their control. Not only are economic decline, severe unemployment, and the unavailability of 'good jobs' associated with the presence of street gangs, but with their transformation into 'economic gangs' (including drug gangs) and with ethnic, racial, and class-related identities and antagonisms that lead to other types of collective violence (Hagedorn, 2008; Pitts, 2000). These same forces alter both intergang relationships and relationships between gangs and their communities.

Research Trends and Needs

Research and theory concerning gangs, and effective means of controlling the violence and crime associated with gangs, are hampered by the lack of a viable typology of youth groups and groups comprised of young adults that would situate the many observed variations of gangs and gang-like groups within broader collective forms of behavior. Comparative research in many countries suggests that distinctions among and between such groups vary a great deal, and that the meaning and function of behavioral variations lack universality.

Varying definitions, meanings, and behaviors have consequences. To the extent that gangs and gang membership confer 'master status' on groups and individuals – among law enforcement personnel, in media portrayals, and among the general public – they contribute to the deterioration of relationships between economic, racial, and ethnic groupings and between the generations. Reification and demonization of gangs, by media, law enforcement, the public, and occasionally by scholars, for example, may contribute to gang problems rather than to their solution.

Self-reported gang membership nonetheless appears to provide a robust measure of gang involvement (Esbensen et al., 2001), supporting continued use of survey research, the primary means of estimating the prevalence of gangs and gang membership, and for identifying the antecedents and consequences of gang involvement. Surveys of youth have shown, for example, that male and female gang members tend to attribute their involvement in gangs to similar factors, such as having gang-involved friends and family members or a desire for protection, a sense of belonging, status, and/or support in coping with boredom and the exigencies of growing up under harsh social and economic circumstances. Moreover, suggesting something more to gangs than "birds of the feather flocking together," longitudinal surveys that track youth over time indicate that delinquent behavior, by girls as well as boys, increases during periods of active gang membership, independently of peer delinquency and compared to both prior and subsequent periods of reported nonmembership in gangs. In addition, multisite prospective survey data from evaluations of two recent school-based law-related education programs, Gang Resistance Education and Training and Teens, Crime, and the Community and Community Works, reveal that onset of gang membership significantly predicts techniques of neutralizations and unstructured socializing with peers, which, in turn, significantly predict delinquency six months later. These data also show that higher rates of unstructured and unsupervised socializing among gang members increase their risk of general (but not serious violent) victimization (Taylor et al., 2007, 2008) and that, consistent with findings from the Mobile (Alabama) Youth Survey in high-poverty

neighborhoods (Spano et al., 2008), gang members are more likely than other youth to adopt a delinquent lifestyle, which places them at increased risk of victimization regardless of whether or not they joined the gang for protection or feel safer as a result of their gang affiliation (Melde, 2009; Melde et al., 2009; Peterson et al., 2004).

Despite such advantages, self-reports have been criticized for failing to provide a realistic appreciation of peer delinquency and the *group* properties of gangs and gang crime (see Kreager et al., 2011). Gang researchers thus are turning increasingly to social network analysis, demonstrating the utility of the method in studying gang boundaries and networks of resource acquisition, leadership, and influence (Fleisher, 2006; McGloin, 2005; Papachristos, 2006; see also Kreager et al., 2011), the structure of inter-gang murder networks (Papachristos, 2009), and relationships between network position within the gang and criminal involvement and desistance from gang membership (Pyrooz et al., 2013; Roman et al., 2012). Additional research is needed to understand how the nature of ties both between and within gangs influences, and is influenced by, the attitudes, resources, and behaviors of individual gang members. However, this will require specialized data on relational ties from a census of all, or at least all core, members of more than a single gang or two; and none of the standard methods of accessing and studying gangs is well suited for this purpose.

Perhaps the best opportunity to study the relationship between group variables and individual behavior is provided by comprehensive detached worker programs. These programs fell out of favor in the 1970s, however, having been replaced largely by law enforcement and legal suppression efforts (e.g., California's Street Terrorism and Prevention Act). Neither of the two most well-known exceptions – Irving Spergel's Little Village project in Chicago (adapted and applied as the 'Comprehensive Community-Wide Approach to Gang-Prevention' in Mesa and Tuscon, Arizona; Riverside, California; and San Antonio, Texas) and the Boston Gun Project (applied to gang violence as Operation Ceasefire in Boston, Chicago, Cincinnati, and Indianapolis) – included a research component consisting of systematic analysis of relational ties within and between individual members of differing gangs. The Boston Gun Project did, however, collect valuable information about networks of violence at the gang level.

A second option is to analyze 'old' data from studies emerging out of the wave of intervention efforts in the 1950s and 1960s, including the Group Guidance Project in Los Angeles (Klein, 1969, 1995), the Midcity Project in Roxbury, Boston (Miller, 1962), and the Program for Detached Workers of the YMCA Metropolitan Chicago (Short and Strodtbeck, 1965). Short and Strodtbeck's study was unique in that it was intended to test theoretical propositions rather than evaluate the program with which their research was associated, but all three studies relied on detached workers to gain access to multiple groups of youth defined as *gangs*. Fortunately, data from these studies have survived and are being extended and analyzed in new ways that can be expected to shed light on the nature and effect of group processes (Decker, 2012; Hughes and Short, 2005; see also Papachristos, 2006).

Although gangs and gang phenomena have changed a great deal in the decades since these early studies and Thrasher's work in Chicago, there is continuity as well as change in the contexts and processes associated with gang formation, gang involvement, and gang crime and delinquency. The theoretical and empirical challenge is to recognize and account for these influences at all levels of explanation (Short, 1985; McGloin and Decker, 2010). In terms of gang policy, comprehensive efforts guided by well-established principles stand the best chance of success, provided they are implemented properly and expected outcomes clearly communicated and agreed upon by all participants, something that has proven difficult to accomplish in practice. As noted by Klein and Maxson, although the history of gang policy fails to inspire much optimism, "[t]here *is* room for intervention, even successful intervention, if we are willing to diagnose the situation carefully before we act" (2006: p. 208, emphasis in original).

Abstract

Harold Garfinkel made fundamental contributions to twentieth-century sociology and beyond. He created a new and unique field of inquiry, 'ethnomethodology,' to study the everyday methods of practical action and practical reasoning used by members of society to make sense and produce order in their daily lives. Garfinkel and his students dissolved the supposed chasm between common sense and scientific/professional reasoning, unpacked the taken-for-granted existence of society, developed detailed descriptions of commonplace and specialized organizations of practice, and specified how society members assemble and sustain the sense that they live, act, and mean in a shared orderly world.

Biographical Facts

Harold Garfinkel was one of the most original and influential scholars of the twentieth century and beyond. Garfinkel created a new subfield of sociology when he coined the term 'ethnomethodology' ('EM') to refer to the study of the people's methods, i.e., the everyday methods of practical action and reasoning that members of society use to make sense and produce social order in their daily lives. Rather than accepting the presumed existence of social order as a given and treating the orderly features of society as a priori, objective structures disengaged from real-worldly settings and actual contexts of activity, he recommended that the orderly features of social action be treated as the 'contingent accomplishment of socially organized common practices' and as work done by participants in various settings to interactionally produce and interactionally recognize those orderly features (Garfinkel, 1967: p. 33).

Garfinkel was born on 29 October 1917 in Newark, New Jersey, and passed away on 21 April 2011 in Pacific Palisades, California. At the time of his death at the age of 93 years, he was survived by his daughter, Leah, and son, Mark, and by his wife of 65 years, Arlene (who passed away in 2013). Garfinkel attended the University of Newark where he earned a degree in business and accounting in 1939. After graduation, he worked as a volunteer at a Quaker work camp in rural Georgia. This was a transformative experience for Garfinkel and motivated him to pursue graduate training in sociology at the University of North Carolina, Chapel Hill, in the fall of 1939.

While working as a research fellow at the University of North Carolina under the prominent sociologist, Howard Odum, Garfinkel authored his first publication, *Color Trouble* (1940), an insightful short story on the dynamics of segregation in the American south. The story involved a dispute that occurred when an African-American woman refused to sit at the back of a bus as it traveled through Virginia on transit from New Jersey to North Carolina. It was originally published in *Opportunity* magazine in 1940 and later included in a collection of the best short stories of 1941 (O'Brien, 1941). Garfinkel's thesis advisor at North Carolina was Guy Johnson, a sociologist with expertise in the study of race relations. His master's thesis addressed the relationship between race and homicide and was based on extensive fieldwork and review of case files in county courthouses across the State of North Carolina. It was an early and highly innovative examination of how workers provide for the accountability of their records and decisions and the consequentiality of formulating race for case-processing and the social construction of statistics. A version of this work entitled Research Note on Inter- and Intra-Racial Homicide was published in *Social Forces* (Garfinkel, 1949).

Garfinkel continued his studies at North Carolina until being drafted into the Army Air Corps in 1942.

After serving in World War II, he was admitted to the first postwar class of graduate students at the newly formed Harvard Department of Social Relations. Garfinkel started his doctoral studies with Talcott Parsons, and also worked with such luminaries as Jerome Bruner, Gordon Allport, Robert Bales, and Pitirim Sorokin. Parsons was a major figure of twentieth-century sociology who sought to revolutionize sociology by integrating the work of Durkheim, Weber, and others into a new and general 'theory of social action' that would not exclude consideration of 'subjective' phenomena. Parsons believed that patterned social action and society in general were structured by a relatively limited number of rules, norms, and values. The society and culture delineate the relevant rules, norms, and values and, once internalized by society members through proper socialization, people accept their priority and seek out culturally valued goals by selecting among socially approved means, thereby structuring their conduct in accordance with how persons are expected to act in specific situations. The norms and values of a society are treated by Parsons as causes of action that become institutionalized and attain continuity as stable, orderly, and constraining features of the society. Although Garfinkel accepted the 'problem of social order' as the fundamental question for the human sciences, he rejected Parsons' theoretical solution that accounted for social action and order in terms of internalization of collectively shared norms and values. For Garfinkel, Parsons' abstract formulation of social reality was not a solution to the problem of social order. Instead, the solution was to be found in a descriptive and practical orientation that would respecify the problem of social order and 'social facts' as members' practices.

From 1946 to 1951, while writing his dissertation in Cambridge, Massachusetts, Garfinkel was significantly influenced by phenomenology, and especially by two phenomenological philosophers, Aaron Gurwitsch and Alfred Schutz. He met regularly with Gurwitsch to discuss phenomenology

and specifically Gurwitsch's then untranslated book, *Field of Consciousness* (1964). He also exchanged letters with Schutz and sometimes traveled to the New School for Social Research in New York for tutorial sessions with him on various topics related to sociology and phenomenology. Garfinkel was intrigued with Gurwitsch's phenomenological respecification of the Gestalt theory of form, including how meaning is determined as functional significations in a context and in part–whole relationships, with the part and whole being mutually constitutive of each other (Gurwitsch, 1964). These ideas were precursors to Garfinkel's recovery of the 'documentary method of interpretation' as a sense-making procedure from Karl Mannheim, who first introduced it in 1952 (Garfinkel, 1967: Chapter 3). Garfinkel credited Gurwitsch with his own prevailing interest in the 'achieved coherence of objects' (Garfinkel and Weider, 1992: p. 206 ftn. 11). The phenomenological ideas of Merleau Ponty's phenomenology of perception and his investigations of embodied action in context and space (Merleau Ponty, 1962) were of particular interest to Garfinkel and later ethnomethodologists, notably David Sudnow (1978) and Douglas Macbeth (2012). Garfinkel explicitly misread phenomenological texts to empirically investigate phenomena of social order and ultimately to further the interests of EM. His dissertation entitled The Perception of the Other: A Study in Social Order used Schutz's phenomenology of the 'life world' and concept of the 'attitude of everyday life' to critically work out Parsons' theory of social action and was completed in 1952. Later that year, Garfinkel traveled to Ohio State University to work on a project researching leadership on airplanes and submarines. When funding for this project ran out in 1953, he went to Witchita, Kansas where he observed trials, conducted postverdict interviews with jurors in the federal district court, and analyzed tape-recorded jury deliberations as part of a University of Chicago Law School study which came to be known as the 'American Jury Project' (Garfinkel, 1967: Chapter 4).

In 1954, Garfinkel joined the sociology faculty at the University of California, Los Angeles ('UCLA') in its early decade. At UCLA, he impacted the views of generations of students and faculty colleagues and sometimes transformed them into cohorts committed to his ideas. He also received frequent invitations to deliver lecturers, conduct seminars, and give plenary talks at professional conferences worldwide, including a series of seminars at the University of Paris in 1995 and an invitation to deliver the Alfred Schutz Memorial Lecture at the meeting of the Society for Phenomenology and the Human Sciences in 2004. Garfinkel was Simon Visiting Professor of Sociology at the University of Manchester in the UK in 1973, an invited fellow at the Center for Advanced Study in the Behavioral Sciences at Stanford University from 1975 to 1976, and a visiting fellow at the Center for Socio-Legal Studies, Oxford University from 1979 to 1980.

Ethnomethodologists and conversation analysts have met regularly for international conferences beginning in 1973 at the University of Manchester, where William ('Wes') Sharrock and other ethnomethodologists have built a long and lasting legacy of research and teaching in EM. Subsequent meetings have been held in the United Kingdom (at Oxford University) and in the United States, including at Boston University and UCLA. The 'International Institute for Ethnomethodology and Conversation Analysis' was formally established in 1989 and has held international conferences in The Netherlands (Amsterdam), England (Manchester), Japan (Tokyo), Switzerland (Fribourg), and Canada (Waterloo). The American Sociological Association accorded official Section status to Ethnomethodology/Conversation Analysis in 2005.

Garfinkel was based at UCLA faculty for over 50 years and, for four decades, UCLA has been the world's leading center for EM and its offshoot, conversation analysis (including institutional talk, Drew and Heritage, 1992). In classrooms and seminars, Garfinkel was a masterful teacher who inspired students and changed lives on a regular basis and whose longevity and passion made him a local legend. Although he retired in 1987, he continued to give public lectures and teach seminars at UCLA and elsewhere for many years thereafter and remained professionally active until shortly before his death. Even after more than half a century of teaching and research in EM, Garfinkel never seemed to lose his enthusiasm or burn out.

He received the Cooley Mead award from the American Sociological Association for his lifetime contributions to social psychology in 1995, was awarded the degree of Doctor of Letters honoris causa by the University of Nottingham in 1996, and received the Liftetime Achievement Award from the Ethnomethodology/Conversation Analysis Section of the American Sociological Association in 2007. At the time of his passing, Garfinkel was working on an unfinished book tentatively entitled, *Lebenswelt Origins of the Sciences* (Garfinkel, 2006). He also left behind an extensive body of unpublished materials including papers, transcribed lectures, and tape-recorded lectures and conversations with students and colleagues. Garfinkel's landmark publication, *Studies in Ethnomethodology* (*Studies*, 1967, reprinted in 1984) remains his seminal work and is EM's primary text.

Garfinkel's Local Cohort of Students and Colleagues

EM represents a radically different understanding of the problem of social order and structured social action. Garfinkel's groundbreaking work provided the source and context for understanding the work of others who came later and whose work was encompassed under the banner of EM. Much of this work was done by Garfinkel's students and colleagues at UCLA and UC Irvine. His earliest cohort included Harvey Sacks, Emanuel Schegloff, and Gail Jefferson (who founded the subfield of conversation analysis ('CA'), Sacks et al., 1974). Garfinkel's idea that people in society organize their activities to be mutually intelligible and recognizable to each other on specific occasions and in actual contexts of activity inspired the development of conversation analysis. The 'indexicality' of meanings communicated in particular situations, how people make inferences, the real-time, contingent character of social action, and the consequentiality of breaching the expectancies of daily life were ethnomethodological insights underpinning CA. Conversational analysts study orderly phenomena in ordinary conversation and look at 'conversational structures,' like turn taking and sequence structure, adjacency pair organization (e.g., question/answer), story-telling structure, and the negotiation of preferences (e.g., preference to accept rather than decline an invitation). CA proposes that the turn-taking system

and other publicly available conversational structures comprise a relatively limited number of 'constitutive rules' that organize how members of a society do a social/speech act and interpret talk (e.g., how to do a 'greeting' and under what circumstances). From this perspective, turn taking in conversation is a normative system oriented to by interactional participants who tend to conform to its specified rules (e.g., 'one-speaker-at-a-time') and to treat departures from these rules as sanctionable violations. For Garfinkel, 'one-speaker-at-a-time' (or any other orderly phenomena in conversation) is premised on the production and recognition of just what talk is mutually oriented to as a 'conversation' in the first place, without resort to concepts of rules or rule systems.

At UCLA, Garfinkel also influenced the ideas of his colleague Melvin Pollner, especially Pollner's work on 'mundane reasoning' (1974, 1975, 1987). While Garfinkel's breaching experiments explored the practices of sense-making by manufacturing fractures in the sense of collectively shared reality, Pollner (1974, 1975) examined naturally occurring settings "that foster interpretive asymmetries … as a matter of course," especially organizational settings, such traffic court sessions or psychiatric observations of 'delusional' patients (Lynch, 2012b: pp. 70–71). Despite disagreements in these settings among experiencers and observers of events about what actually happened, Pollner found that what results is not an agreement that multiple worlds exist, but rather the use of several members' practices to reconcile the competing versions. His analysis of 'reality disjunctures' (Pollner, 1979) elaborated the presumed existence of a single, world-known-in-common that operates as an unyielding background expectancy and is sustained even "in the face of obstinate disagreement about it [or] … any momentary anomaly or disjuncture" (Lynch, 2012b: pp. 69–70).

Among Garfinkel's earliest graduate students at UCLA were Egon Bittner and D. Lawrence Wieder. The collaborative work of Garfinkel and Bittner (reported in Chapters 6 and 7 of *Studies in Ethnomethodology*, Garfinkel, 1967) represents a fundamental contribution to professional sociology's interest in 'organization,' as well as "innovations in the study of coding and classifying, and the agenda for and use of textual records in sociological inquiries" (Slack and Carlin, 2013: p. 2). Wieder's dissertation (published in 1974) was an ethnography conducted among residents, staff, and Wieder (as the researcher) in a half-way house for paroled drug offenders. The study described the relevance of 'telling the convict code' in that setting and developed the ethnomethodological idea of rules as methods for formulating settings. Wieder showed that reference to the maxims of the 'code' (e.g., do not snitch; do not interfere with other residents' interests; do not trust staff) was a consequential social practice that served to persuasively structure the sense-making and practical action in specific circumstances, but that its use in providing for the accountability of conduct could also be challenged by those present in the half-way house.

EM reconsiders "what it means to produce observations, descriptions, and explanations of something 'actual'" (Lynch, 1993: p. 113). It has no imperative or prohibited set of research procedures or methods, so long as the data obtained is adequate to the particular phenomena under investigation. The idea is "to identify the practices through which social order is performed in everyday life" (Lynch, 1984: p. 333). The widespread availability and increasing use of audio-video recording technology in the 1970s enabled ethnomethodologists to record and study the social world and its activities in real-time and contingent audio-visual detail, yielding unprecedented discoveries of the everyday methods for producing social order. EM details the sights and sounds of real-worldly affairs and can help the human sciences do better job, in a manner akin to using a more powerful microscope (Heath, 1986: p. 4): "The point was to recover a kind of technical 'oriented to' sense of spontaneous communicative actions" (Lynch, 1984: p. 334). When ethnomethodologists examined social activity in greater detail, they found that they would lose the phenomena, if they did not see it in operation. Currently, there are two active and productive branches of ethnomethodologically informed research: conversational analysis (e.g., Sacks et al., 1974), including 'institutional talk' (Drew and Heritage, 1992), and ethnographic studies of workplace activities. 'Studies-of-work' focus on the practical action and tasks of participants in different settings – on what people are trying to do and how they are doing it.

From the late 1970s onward, Garfinkel encouraged his students to investigate specialized domains of scientific, professional, or technical practice and to conduct 'hybrid studies of work' that would cross traditional academic boundaries, forming the basis for interdisciplinary cross-fertilization between EM and other disciplines (Burns, 2001, 2009; Livingston, 1986; Lynch, 1985, 1993; Macbeth, 1996, 2012). As part of Garfinkel's 'unique adequacy requirement of methods,' several of his students attempted to master the technical practices of particular fields of inquiry before explicating their local organization, raising the question of whether researchers must 'go native' to be able to understand and know how to produce/reproduce the materially detailed work constituting a specific domain of scientific, technical, or professional practice. Garfinkel's recommendation to 'hybridize' EM with other disciplines, such as mathematics, the natural sciences, or law, was part of his ambitious studies-of-work program in which "the long-term aim was not only to enrich the sociology of the sciences, arts, and other occupations and preoccupations, but [that] … ethnomethodology would take a distinctive form as it became integrated with the pedagogies and practices of music, law, medicine, mathematics, and so on" (Lynch, 2012a: p. 165).

The studies-of-work of Garfinkel and his students self-consciously set aside conventional theories of social action and order and "proposed a radically new approach to studies of workplace activities, including work in the sciences and technical professions, which would encompass the contents of practices, and not only the organizations that would trace back to sociology's toolbox of concepts and variables" (Lynch, 2012a: p. 165). These studies turned the theoretical problem of social order into a practical procedural problem: "In ethnomethodology, 'procedural' means labor of a certain incarnate methodological sort: at the workplace, progressively and developingly coming upon the phenomenon via the work in … the … directly observed phenomenal field detail of producing it" (Garfinkel, 1996: p. 10, ftn. 11). What Garfinkel called the 'corpus' of ethnomethodological studies-of-work includes Michael Lynch's research in scientific

laboratories (1985, 1993), Eric Livingston's investigation of mathematician's work (1986), Britt Robillard's study of medical practice and the 'lived experience' of disability (1991), Kenneth Liberman's examination of philosophical debates among Buddhist scholar-monks (2004), Douglas Macbeth's studies of educational settings (1996, 2001), and Stacy Burns's research in legal contexts (2001, 2009).

Short Description of Garfinkel's Major Works and Publications

Garfinkel's early work in the 1950s and 1960s was strongly influenced by Alfred Schutz and the practical questions he asked about 'verstehen,' or how people come to achieve inter-subjectivity and create a world of mutual understanding. For Schutz (1962), the maintenance of a world-known-in-common relies on society-members knowing and using 'common understandings' and typified 'recipe knowledge' to engage in practical courses of action on a moment-by-moment basis. His belief that the 'attitude of everyday life' had an organized structure governed by cognitive norms was based on the idea that members' knowledge and skills exist prior to actual situations and that social order and human action could be investigated independent of actual social contexts and contingencies. Garfinkel's publication on 'trust' (1963) relied on Schutz's notions of 'background expectancies' and the maintenance of the 'reciprocity of perspectives' to make social life work and what it is to ourselves and others. For Garfinkel, the notion of 'member' suggested that people who belong to a specific society possess knowledge of the "socially-sanctioned-facts-of-life-in-a-society-that-any-bona-fide-member-of-the-society-knows" and can trust that others in society also know (1967: p. 76). 'Trust' was "compliance with the expectancies of the attitude of daily life as a morality" (1967: p. 50, ftn. 5). It permeated not only the intelligibility of mundane affairs, but also their moral accountability. In his famous breaching experiments, Garfinkel would use a series of experiments to demonstrate the fragility of trust, along with "the suspension of indefinite possibilities of mistrust … that maintains normal social order in the absence of unequivocal rules" (Lynch, 2012a: p. 164; Garfinkel, 1963).

Chapter 1 of *Studies in Ethnomethodology* described EM's unique and distinctive subject matter as an essentially unexplored domain of phenomena: the situated production of social order. To investigate this domain, Garfinkel recommended that the stable and organized features of ordinary settings and activities be treated as the contingent achievements of the participants to those settings and actions. In presenting this new understanding of society and social action, he not only provided a revealing correction on what had previously been presented by virtually every other conventional theory of social order, but also set forth an incommensurably alternate research agenda.

In Chapter 2 of *Studies*, Garfinkel reported the findings from his so-called 'breaching experiments,' in which the experimental procedure was "to start with a system with stable features and ask what can be done to make for trouble" (Garfinkel, 1963: p. 187). The familiar, taken-for-granted routines and background understandings of households, retail businesses, or children's games were suspended in these exercises by student-researchers who undertook to act like a polite lodger in their own home ignorant of the informal routines, or to violate the 'institutionalized one price rule' at a retail store by bargaining over prices (Garfinkel, 1967: p. 69), or to disregard the rules of play in a game of tic-tac-toe. These disruptions produced much anxiety and indignation in the research subjects, demonstrated the unraveling of trust, and prompted "reflections through which the strangeness of the obstinently familiar world can be detected" (Garfinkel, 1967: p. 38). The breach provided a 'perspective by incongruity,' which made visible the assumptive and otherwise unnoticed orderliness of normal environments and offered first-hand access to their constitutive practices, such that "[p]aradoxically, the breach constituted the presumption of the prior agreement" (Lynch, 2012a: p. 164).

In Chapter 3 of *Studies*, Garfinkel explored how background knowledge is relied upon and used by society-members in everyday life in a manner akin to the 'documentary method of interpretation.' The 'method,' according to Garfinkel, consisted of treating actual appearances as standing on behalf of a presupposed pattern. But not only were the appearances used to infer the pattern, the pattern was also utilized to decide what the appearances were appearance of. Garfinkel designed several experiments to show the documentary method in operation. In one experiment, student research subjects attempted to receive counseling by asking questions they understood a 'counselor' would answer either 'yes' or 'no' (Garfinkel, 1967: pp. 79–80). The subjects asked a series of questions, received a response, and then asked another question, tied to the answer they had received to the prior question. Unknown to the subjects was the fact that the answers were predetermined according to a table of random numbers. Nonetheless, the subjects were able to get through the question-answer interchange and believed they had participated in a meaningful exchange in which they had received answers to their specific questions and "advice … for managing their affairs" (Garfinkel, 1967: p. 94). Garfinkel observed that the documentary method was a ubiquitous sense-making device in social life and exhibited the part–whole relationships of a Gestalt context (Gurwitsch, 1964). His exercise also raised important questions about "the validity of the 'underlying patterns' discerned through the use of this method" (Lynch, 2009: p. 89), questions that are broadly relevant to the work of using documents and other 'evidence' in historical reconstruction.

Chapter 4 of *Studies* reported on Garfinkel's earlier research on jury deliberations, to which he attributed the origins of EM. When Garfinkel examined the tape-recorded jury deliberations, he noted that despite the jurors' lack of formal legal training and credentials, they nonetheless diligently engaged in 'methodological' inquiries to assess evidence, decide upon disputed issues, and reach a 'just and fair' verdict in the case (Garfinkel, 1967: p. 105). With this insight, he began a series of lifelong investigations into the relationship between scientific/professional methods and reasoning and 'vulgar' or commonsense reason and methods.

In Chapter 5 of *Studies*, Garfinkel rejected received versions of gender that simply posit its relevance and

explicate a priori cultural assumptions and definitions. Instead, investigated how gender is a moment-by-moment accomplishment and specified the practices of managing one's taken-for-granted social (gender) identity. The subject of the study, 'Agnes' (pseudonym), was a transsexual person who was born with normal male genetalia and raised as a boy until age 17, when he adopted a female gender identity. Garfinkel met her at age 19, after she was referred to the UCLA Department of Psychiatry for counseling and ultimately a sex-change operation (i.e., sex reassignment surgery). Although he found Agnes' appearance to be 'convincingly female' (Garfinkel, 1967: p. 119), she regarded her efforts to 'pass' unquestionably as female as 'tests,' requiring her to become a quick study and to use constant diligence so her secret would not be revealed. Notwithstanding that gender is usually considered to be dichotomously determined at birth, as either male or female, Garfinkel's investigation made perspicuous the infinitely many, yet otherwise 'seen-but-not-necessarily-noticed,' ways that social (gender) identity is done, recognized, and made accountable in almost every facet of daily life.

In Chapter 6 of *Studies*, Good Organizational Reasons for 'Bad' Clinic Records, Garfinkel described a study conducted with Egon Bittner and aimed at developing a systematic empirical account of patient pathways through a medical clinic. Relying on clinic records as the primary data, he highlighted the many problems that were encountered by researchers in using the records (e.g., information recorded in files was not standardized, file folders were incomplete, and information of importance to the researchers was missing). Yet instead of abandoning the study, or reporting its findings directly, Garfinkel turned his attention to the 'good organizational reasons' for the deficient clinic records and described how clinic staff 'managed' the records and case files to document their activities. His analysis offered a powerful conceptual tool for investigating 'the substantive production of history,' by "transform[ing] the historian's problem into a substantive, constitutive phenomenon … a matter of producing documents, withholding details, and collecting them into files before any investigator gets hold of them … " (Lynch, 2009: p. 92).

Chapter 8 of *Studies* relied on Schutz's work to explore 'the rational properties of scientific and commonsense activities.' While Schutz "drew a strict demarcation between scientific theory and scientific practice and between scientific and commonsense rationality" (Lynch, 1993: p. 134), Garfinkel found that "'commonsense' rationalities were included in the principles and operative practices of science [and] provided a radical antidote to the idea that commonsense was the domain of 'prescientific' notions" (Lynch, 1993: p. 139). He thereby "pluralized 'rationality'" to become "the rationalities of science and commonsense" (Lynch, 2012b: p. 72) and deprivileged scientific/professional over lay knowledge and competencies (Lynch, 1993: p. 139). Unlike Schutz, Garfinkel asked how 'rationality' and intersubjectivity are achieved in actual contexts of activity. He worked out the 'properties of rationality' by using the phenomenological method of bracketing the taken-for-granted, objective existence of 'what is really going on,' instead treating it as 'empirically problematical material' (1967: p. 282) and as researchable things. Garfinkel also diverged from Schutz's treatment of science and other practical action as governed by distinctive cognitive norms (Lynch, 1993: pp. 140–141) and demonstrated the intertwining of scientific (or technical/professional) knowledge and expertise with commonsense knowledge and competencies (e.g., Burns, 2001, 2009).

In a later publication on 'Ethnomethodology's Program' (Garfinkel, 1996), Garfinkel explicitly linked EM to the work of Emile Durkheim and particularly to what he termed Durkheim's 'aphorism,' that "the objective reality of social facts is sociology's fundamental principle" (Durkheim, 1895/1982). Garfinkel subsequently clarified this connection, stating (as only he could put it) that "ninety years of Durkheim scholarship … missed from the beginning … that the objective reality of social facts was a stand in for every topic of logic, meaning, reason, method, and order in intellectual history specified as an achieved empirical phenomenon of immediate, unmediated…practices, production, recognition and witness" (Garfinkel, 1998, Course Announcement, 'Ethnomethodology,' UCLA Sociology Department). According to Garfinkel's intentional misreading of Durkheim, 'social facts' were to be reinvestigated and respecified by EM as situated practical achievements and work-site practices.

Perhaps not surprisingly, given this alternate reading and 'respecification' of Durkheim, recent writings have attempted to trace the origins of EM back to Durkheim's 'classic' scholarly program (Rawls, 1997), or to tie EM to the initiatives of American pragmatist theorists (Erylbaum and Maynard, 2011). The suggested link with pragmatism is apparently based on its call for the recovery of concrete practices and focus on language use in actual situations (Erylbaum and Maynard, 2011). However, such attempts to link EM back to 'classic' theories (Durkheimian or pragmatist) seem puzzling for some EM scholars because Garfinkel insisted throughout his career that EM makes a 'radical break' with formal theory and analysis and instead provides foundational analyses of society-members' everyday routines and practices for achieving social order. Both Durkheimian and pragmatist formulations leave essentially unexplored and unrecoverable the core phenomena of ethnomethodological interest: the situated organization of practical tasks and activities. To paraphrase Garfinkel, such formulations are not a solution to the problem of social order. Rather, the real-worldly affairs that sustain the professional interpretations are lost in the interpretations and neither Durkheimian nor pragmatist theorists have an interest in how social order is produced and achieved, or how it could be taken seriously, analytically, or descriptively.

For many years and until fairly recently, *Studies in Ethnomethodology* was Garfinkel's only book, so to a large extent his legacy and contribution are "embodied in the work of others on whom he had a profound influence" (Lynch and Sharrock, 2003: p. x) and who pursued his research agenda. EM's productivity as a research approach is evident in a wide range of studies-of-work conducted by Garfinkel and his students in a diverse variety of settings. This corpus of EM studies is represented in an early collection of definitive works (Turner, 1974) and in two more recent, multivolume

collections of ethnomethodological work (Lynch and Sharrock, 2003, 2011).

Lasting Impact of Garfinkel's Work

Garfinkel revolutionized the field of sociology and the human sciences more generally when he founded EM as a discipline for investigating "members' ordinary practices for assembling intersubjectively accountable worlds" (Macbeth, 2001: p. 48). Rather than providing causal explanations or predictions, Garfinkel and his students developed detailed descriptions of commonplace and specialized organizations of practical action and practical reason that went beyond sociology's existing toolbox of concepts and variables. His ground-breaking insights into how people in society 'make sense' dissolved the supposed chasm between common sense and scientific/professional reasoning, unpacked the taken-for-granted existence of society, and specified the practices by which people produce and sustain the orderliness of their everyday activities and the sense that they live and mean in a shared orderly world.

In seminars and classes, Garfinkel sometimes played a videotape for students to demonstrate the difference between the 'lived work' of a practice (Garfinkel, 1989) and theorized versions of it. The video showed a student typing at the keyboard while speaking a moment-by-moment commentary on exactly what she was doing as she typed. The tape made evident an influx of detail (e.g., a variety of pauses (to think of something to say, or stop from running off the page), backspacing to cross out a passage and restart it, etc.). Garfinkel proposed that the videotape of the 'lived work' of typing and the resulting typed document were 'asymmetric alternates' to each other, just as EM was to an 'asymmetric alternative' to virtually every other existing formal theory and analysis of social action and order. While "one could derive from the video how the final text was composed in a continuously unfolding series of actions, … one could not read the final typescript in isolation and recover the 'lived work' that produced it" (Lynch, 2012a: p. 166).

Garfinkel's exercises on 'instructions' and 'instructed action' (Garfinkel, 1989, 2002) further elaborated this ethnomethodological property of 'reflexivity,' i.e., treating the features of a setting and the action in that setting as situated accomplishments of the participants to that setting and activity. The exercises involved students following a variety of instructions, such as instructions for assembling parts into a finished chair, or making a way-finding journey to someone's home by using an 'occasioned map,' or complying with a simply request like 'sit over there' while wearing inverting lenses (which made problematic doing even the most routine things in seemingly familiar environments by literally turning the familiar world upside down (Garfinkel, 2002)). In each case, he showed that there was something more to the present sense, meaning, order, relevance, reason, and method of the instructions for the user than the written text or verbal instructions provided, and that this 'what more' was a reflexively embedded, *in vivo* detail of the constitutive practices that made up the course of following the instructions, or instructions-in-use (Garfinkel, 1989, 2002). EM addresses the 'instructable reproducibility' of a practice (Garfinkel, 1989) and in this sense its findings "can be likened to manuals of instructions that describe how the practices being studied are produced and performed … [and] delve into non-obvious features of situated conduct that elude rule-governed models and cognitive schemes" (Lynch, 1984: p. 334).

The corpus of EM studies demonstrates a radically unorthodox understanding of the 'objective reality of social facts' and 'immortal ordinary society': an independently existing world of specific occasions, practical tasks, embodied skills, and contexts of activity. As Garfinkel described EM, it "is concerned with 'What More' immortal, orderly society could possibly consist of, as the locus and the setting of every topic of order, every topic of logic, of meaning, of method, specified and respecifiable as the most ordinary Durkheimian things in the world" (Garfinkel, 1996: p. 6). Of course, just what that could mean is only to be found in the material examination of actual cases, as Garfinkel always insisted.

Abstract

An interconnection between psychological and gastrointestinal (GI) functioning has long been recognized, incorporating multiple mechanisms and considering bidirectional processes. However, exciting discoveries regarding the role of stress and depression in etiology and disease course have shed new light on the understanding of biopsychosocial processes in chronic GI conditions. This article provides an introduction to GI tract functioning, GI disorders, and stress mechanisms in the gut, followed by an overview and discussion of the psychosocial impact of these disorders, the role of stress and mental comorbidity in GI disorders, and the current knowledge regarding psychological interventions for GI disorders.

Background

Historically, a link between psychological and gastrointestinal (GI) functioning has been well recognized. The term 'nervous diarrhea' started appearing in medical texts in the mid-1800s. In the early 1900s, physiologist Walter Cannon observed that emotional calmness was important to normal digestion, and speculated that mental distress may contribute to disturbed digestion. For several decades in the twentieth century, there was a predominant view that psychodynamic conflicts played a central role in the cause of ulcerative colitis, an inflammatory bowel disease (IBD), supported in part by Cecil Murray's published case reports in 1930. This link between psychology and gut functions has worked its way into folk wisdom and common language, with expressions such as "that took a lot of guts" and "butterflies in the stomach." The contemporary understanding of the interplay between psychological functioning and GI disease is much more complex, incorporating multiple mechanisms and considering bidirectional processes.

The next sections provide an introduction to GI tract functioning, GI disorders, and stress mechanisms in the gut, followed by an overview and discussion of the psychosocial impact of these disorders, the role of stress and mental comorbidity in GI disorders, and the current knowledge regarding psychological interventions for GI disorders.

The GI Tract and the Brain–Gut Axis

The human GI tract extends from the mouth to the anus, and includes the esophagus, stomach, approximately 13 feet of small intestine, and 7 feet of large intestine. The GI tract has a crucial role in survival, as it is responsible for breaking down food, extracting nutrients, exchanging fluids, and expelling waste. It is a dynamic organ that actively moves contents through the tract using coordinated ripple-type muscle contractions. A microworld of bacteria, known as the gut flora or gut microbiota, exists throughout the GI tract, and facilitates the breakdown and processing of foodstuffs. This is the most highly innervated organ in the body, and has the largest concentration of neurotransmitters outside the brain, including approximately 90% of the body's serotonin, supporting the view of a highly developed brain–gut communication pathway. The GI tract is regulated through its own internal nervous system, the enteric nervous system, and the central nervous system, via a complex interaction of the neuro–endocrine–immune systems, with the autonomic nervous system playing a central role in brain–gut communication (Bonaz and Bernstein, 2013).

This bidirectional connection system is known as the brain–gut axis. While gut action typically occurs without much awareness or focus, visceral afferent information from the GI tract has been shown to be more available to conscious awareness than other body systems (e.g., cardiovascular). Actions including gastric emptying, transit time, and small and large intestine contractions can be altered by psychological processes such as emotion and stress (Mayer et al., 2001). Certainly, gut upset (e.g., loose stool, nausea) is a common experience for many when stressed.

Organic and Functional GI Disorders

Many of the disorders of the GI tract are attributed to motor or sensory disturbances. The GI disorders are typically categorized as organic or functional; the organic disorders are those defined by structural or inflammatory abnormalities, and the functional disorders reflect chronic or recurrent GI symptoms in the absence of these abnormalities, suggesting a problem in the functioning of the gut. While the functional disorders are not typically associated with greater health morbidity or mortality, the organic disorders can be. Regardless, both types of GI disorders result in significantly poorer quality of life even compared to those with other chronic diseases, affecting social, personal, and work domains of functioning.

Organic GI disorders include the acid peptic diseases (e.g., gastroesophageal reflux disease) and IBD. IBD is characterized by recurring inflammation in the GI tract leading to abdominal pain, bloody diarrhea, and fatigue. IBD has been increasing in prevalence in recent decades, with current estimates as high as 500 per 100 000. The peak incidence is in young adulthood (second and third decades); however, 25% of new cases are diagnosed in children and adolescents. While IBD is clearly less

common than its functional counterpart, irritable bowel syndrome (IBS), it can be difficult to achieve and maintain remission for this condition, and it often requires costly medication and surgery for disease management. Although rare, it can also be associated with mortality. The pathogenesis of IBD is thought to involve an exaggerated immune response to normal microbes in the intestine, triggered by environmental factors in those with a genetic susceptibility.

Functional disorders are generally more prevalent than organic, with IBS the most common type. IBS is a chronic relapsing condition involving bowel habit disturbance and lower abdominal pain or discomfort. It affects approximately 10–20% of the adult population, has peak onset in the 30s and 40s, and is one of the 10 most common reasons to visit the primary care physician. Nonulcer dyspepsia, with an estimated prevalence of 12–15%, is an upper gut disorder with symptoms of pain, bloating, and nausea; the symptoms are similar to those of an ulcer, but investigation (upper endoscopy) does not show an ulcer to be present. It is thought that these conditions arise because of sensory nerve disturbances along the brain–gut axis.

Stress and GI Disorders

While many of the GI disorders have differing etiologies, clinical and experimental research suggests that stress may be a common risk factor affecting disease course, and comorbid psychological disturbances may be higher for those with GI disease than the base rate in the community, as detailed in the next sections. It is thought that the special link between the brain and gut, and in particular, disruptions in communication along the brain–gut axis, may help to explain these associations (Bonaz and Bernstein, 2013). Altered gut motility and visceral sensitivity have been seen as fundamental processes in the modern understanding of functional GI disorders. Regions in the brain that regulate emotional and cognitive functions, including the amygdala, hippocampus, and prefrontal cortex, are also involved in modulating gut function (Mayer et al., 2001).

Experimental research suggests that stress can prompt a range of GI tract disturbances such as increased intestinal permeability, mucosal inflammation, and gastric ulcers (Caso et al., 2008). At cell level, mucosal mast cells, and at endocrine level, corticotrophin-releasing factor have a central role in immune system changes and inflammation of the mucosa. The autonomic nervous system is highly sensitive to emotional and evaluative input (e.g., the 'fight or flight response'). Recent work suggests that there may be autonomic dysfunction in individuals with organic or functional GI disorders, although the specific nature of the sympathovagal balance, including parasympathetic hyporeactivity, may be different among disease types (Pellissier et al., 2010). Finally, the gut microbiome is just beginning to be explored as another pathway through which psychological processes such as mood disorders may interact with gut function. Converging research is suggesting that intestinal microbes might be involved centrally in modulating behavior and brain chemistry, and that environmental influences such as stress can affect the microbial balance in the gut (Bercik et al., 2012) (**Figure 1**).

Figure 1 Psychoneuroimmunological pathways in inflammatory bowel disease. Stress, via the limbic system, stimulates the HPA (a) and the ANS (b) leading to the production of CRF, ACTH, and then cortisol and the catecholamines. Noradrenaline is also released directly into the gut mucosa from sympathetic nerve endings of the ENS (c). In addition, mast cells lying close to enteric nerve endings degranulate releasing tryptase, histamine, and other mediators (d). These neuromediators through incompletely characterized mechanisms, including activation of lymphocytes, stimulate epithelial chloride secretion and mucus production, increase paracellullar and transcellular epithelial permeability. Subsequent ingress of luminal bacteria into the mucosa triggers further immune and inflammatory events involving dendritic cells, macrophages, and other cell types. ACTH: adrenocorticotropic hormone; ANS: autonomic nervous system; CRF: corticotrophin releasing factor; ENS: enteric nervous system; HPA: hypothalamic–pituitary–adrenal axis. Psychosocial Impact of GI Disorders

Health-Related Quality of Life

Health-related quality of life (HRQOL) in patients with chronic conditions encompasses the effects of these conditions and associated treatment on physical and psychosocial functioning of the person living with the illness. HRQOL frequently has been found to be impaired in those with chronic GI disorders. For example, a systematic review concluded that HRQOL is significantly reduced in patients with moderate-to-severe IBS, at a level comparable to other chronic disorders such as depression (El-Serag et al., 2002).

In organic GI conditions such as IBD, impaired HRQOL may result from its incurability, unpredictability, and severity of symptoms, surgery, and medication side effects, although psychosocial factors may also play a role. A meta-analysis found that disease-related factors only accounted for 37% of the variance in HRQOL (van der Have et al., 2014). The authors concluded that other variables such as illness perception, sociodemographic factors, and mental health are also contributory, and addressing those which are modifiable could improve the HRQOL. In the functional disorders, diminished HRQOL is attributed to disease-related factors including unclear diagnosis and unavailability of universal treatment, combined with debilitating symptoms and avoidance of potential symptom triggers.

When HRQOL was directly compared between patients with organic and functional GI conditions in a large ($n = 4441$) population-based study exploring self-perceived health status, IBD participants reported poorer physical health, and IBS participants reported poorer mental health and greater levels of stress (Tang et al., 2008), demonstrating the interrelatedness of somatic and psychosocial influences on HRQOL. In many chronic conditions, including GI disorders, disability and poorer HRQOL can be more strongly associated with underlying mental illness or psychological distress than the disease per se, perhaps as depression and/or comorbid anxiety can aggravate disease activity and negatively impact on disease management.

HRQOL can be compromised for young people with IBD as well (Greenley et al., 2010), as the impact of the disease and treatment is evident in the overall development, with common short stature and delayed puberty contributing to a visible difference from peers. Pediatric patients with IBS also report poorer HRQOL compared to healthy peers, although the impact of their disease on time missed from school is not as high as those with organic GI conditions (Varni et al., 2006). For both pediatric IBD and IBS patients, poorer HRQOL is often found to be related to embarrassment resulting from frequent use of toilets and not rarely becoming a target of the 'bathroom humor' by the peer group.

Coping

Coping with chronic illness involves managing demands imposed by the illness. These can include physical and mental symptoms, as well as psychological adjustment to changes in the functioning of the body and the social impact of illness on one's roles within the family and society. Comparing the coping approaches between patients with organic and functional GI disorders, studies disagree on whether IBD and IBS patients differ in their preferred coping strategies. While IBS patients have been found to catastrophize more often than IBD patients in some studies, other research does not demonstrate such interdisease differences, showing that both those with IBD and IBS differ from healthy controls, in that the former tend to rely on passive coping approaches. A comprehensive systematic review found that emotion-focused coping was associated with worse psychological outcomes, while the effect of problem-focused coping was, to some extent, associated with better psychological outcomes in IBD (McCombie et al., 2013).

There is a dearth of data with respect to pediatric and adolescent populations' coping with the disease, with only anecdotal reports of less well-developed coping skills than in the healthy counterparts.

Social Support

Social support involves positive assistance (actual and perceived) from a network of friends, family, and others. High perceived social support has been linked with good health outcomes; this is thought to relate to the practical assistance as well as the emotional support that caring individuals can provide. In patients with chronic GI disorders, social support has not had much research attention. Available studies suggest that those with IBD generally feel well-supported, although this may not be the case for individuals with moderate-to-severe functional symptoms. IBD patients reported more tangible, affective, or emotional support and were more likely to have experienced a positive social interaction compared to their community non-IBD counterparts ($n = 388$) (Rogala et al., 2008). A beneficial effect of social support on disease course has also been reported, with higher social support shown to decrease the likelihood of disease deterioration in IBD (Camara et al., 2011). For IBS patients, stress arising from conflict-laden relationships is reported to be a stronger predictor of IBS outcomes than the benefits arising from positive social support in some studies, suggesting a detrimental effect of poor quality support. Online social support groups, a relatively recent phenomenon, are increasingly being reported as important tools in providing social support for patients with GI conditions (Malik and Coulson, 2011).

Social Functioning and Stigma

People with chronic GI disorders frequently report challenges in social functioning. Preoccupation with toilet availability, and symptoms such as diarrhea, bloating, and gas can make social interactions difficult and may lead to isolation. Stigma associated with bowel function can prevent those affected by IBD and IBS from sharing the information about the diagnosis or their needs regarding symptom management. The nature of GI symptoms, the shame around potential loss of control, and the anatomy focus on the bowel and rectum are taboo in many cultures. Social gatherings often include or revolve around food, which can be an obstacle for those with chronic GI disorders due to self-imposed diet restrictions and avoidance of restaurants resulting from fear of problematic ingredients. Individuals who avoid certain social or professional situations (e.g., visit to a theater or a business trip) may have their actions misunderstood and interpreted as evidence of their lack of dedication or negligence, rather than as a consequence of their illness.

According to the largest study to date ($n = 269$ IBS; $n = 227$ IBD), IBS patients feel more stigmatized than their IBD counterparts, which may be explained by the perception of IBS as being a less 'real' disease given lack of pathological changes to the bowel and lack of effective medical treatment (Taft et al., 2011). Despite this, perception of stigma is more highly correlated with poorer patient outcomes in IBD than IBS. Having a GI disorder can adversely affect employability,

particularly for those with more severe illness or difficulty settling symptoms, resulting in loss of income, fewer career prospects, or unemployment.

Social functioning is also reported to be impaired in young people living with GI conditions. While parents report that their adolescents with IBD function comparably to healthy youth, the adolescents report the opposite; namely that their social functioning is poorer than their healthy counterparts and similar to that of other chronically ill young people (Greenley et al., 2010).

Self-Image and Sexuality

People living with GI disorders, particularly disorders that affect bowel habit, frequently report perceptions of being 'unclean' and concerns about managing bodily odors. While there can be problems maintaining hygiene due to fecal leakage, or in the case of IBD, as a consequence of colectomy, often the perception is only subjective and results from the belief that having a bowel problem makes a person 'unclean.'

Disease-affected body image and self-esteem concerns can fluctuate depending on disease status and life stage. In an Australian study of middle-aged IBD patients ($n = 347$ patients), 67% reported negative body image related to their disease, with both men and women endorsing this self-view (Muller et al., 2010). In addition, women and those who had had bowel surgery were more likely to report decreased frequency of sexual activity and decreased libido. While early studies of self-esteem in young people with IBD suggested that low self-esteem and distorted self-image were common, a recent meta-analysis found no difference in self-esteem levels between IBD patients, healthy controls, and young people with other chronic conditions (Greenley et al., 2010). No similar studies have been identified for functional adolescent or pediatric populations.

In functional GI disorders, and IBS in particular, the majority of studies on sexuality focus on childhood adversity and trauma. When this was first examined, patients with IBS were reported to have very high rates of childhood abuse, including sexual abuse (up to 50%), at a prevalence that was significantly greater than healthy controls. However, these findings have been reexamined and the base rates of childhood abuse in the general population have now been found to be high, so there is some controversy about whether IBS is uniquely associated with sexual abuse. In nonulcer dyspepsia, a higher rate of physical and emotional abuse has been observed when compared with healthy controls; however, very few studies have explored this issue.

Mental Comorbidity

Like other chronic health conditions, GI disorders have been associated with high levels of perceived stress and greater prevalence of mental disorders (e.g., anxiety and depression) as compared to the healthy populations. These psychological difficulties may result from disease burden, but may also be a consequence of common pathways related to dysfunction in the brain–gut axis and interconnection of neuro–endocrine–immune systems as discussed above. Despite some similarities, depression, anxiety, and stress may play a somewhat different role in etiology and disease progression in organic and functional disease and are thus discussed separately.

Depression, Anxiety, and Stress in IBD

Population-based studies have documented a higher lifetime prevalence of depression in IBD compared to the community, with estimated rates of 27 versus 12% (Walker et al., 2008). In pediatric and adolescent IBD populations, prevalence of depression was also found to be higher than for youth with other chronic illnesses (Greenley et al., 2010). There is more uncertainty about a higher prevalence of anxiety disorders in IBD patients. While studies have reported higher levels of anxiety symptoms for IBD patients, lifetime prevalence of anxiety disorders was not found to be greater than for matched controls in a population-based study; panic disorder showed a trend for higher rates (8 vs 4.7%), and social anxiety rates were significantly lower in IBD than controls (6 vs 11%) (Walker et al., 2008). Comparisons of rates with other national samples suggest that IBD patients may have higher rates of panic, generalized anxiety, and obsessive–compulsive disorders.

Anxiety and depression have been understood to be disease sequelae, with impact on disease course rather than causal factors for onset. However, studies have found that depression predated the onset of IBD in many cases, and new experimental work with animal models has demonstrated that inducing depression increases susceptibility to spontaneous intestinal inflammation in mice, raising the possibility of depression as a potential etiological risk factor. With regard to disease course, a review of 11 longitudinal studies of depression in IBD concluded that it negatively impacts IBD course, with effects such as a shorter time to relapse (Rampton, 2009).

There is a growing recognition of the role of stress in IBD disease course, independent of mental disorders. A review of nine longitudinal studies of stress identified a relationship with increased inflammation and IBD symptoms (Maunder and Levenstein, 2008), and recent prospective work confirmed higher stress levels in the periods preceding symptomatic disease flare (Bernstein et al., 2010). In addition, studies in animal models have demonstrated that stress can induce colitis and treating the animal with antidepressants restores vagal function and reduces the intestinal inflammation.

Regarding the role of personality factors in IBD, studies have examined personality traits such as neuroticism, perfectionism, and alexithymia and found them to be more common in IBD patients than their healthy counterparts. However, none of these studies have prospectively evaluated personality prior to disease onset, and these traits can be affected by current emotional state.

Depression, Anxiety, and Stress in Functional GI Disorders

While high rates of mental comorbidity, ranging from 40 to over 90%, have been reported for IBS patients presenting to tertiary care centers (Drossman et al., 2002), population-based studies have clarified that the majority of individuals with IBS do not seek medical care, and are similar to non-IBS

individuals with respect to their mental health. Those with moderate-to-severe GI symptoms tend to exhibit higher rates of anxiety and depression, but it cannot be said with certainty whether anxiety and depression precede or follow the GI symptoms. In contrast, individuals with nonulcer dyspepsia, who do not seek medical care, have been found to have poorer scores on psychological domains than healthy controls, suggesting that psychological morbidity might not be associated with health care–seeking behavior of this group (Van Oudenhove and Aziz, 2013).

Few studies have examined mental health in pediatric or adolescent functional GI patients, so rates of comorbid anxiety and depression in this population are largely unknown. There is currently some evidence that patients with recurrent abdominal pain in childhood have an increased risk of IBS during adolescence and young adulthood, and thus possibly a similar likelihood of developing a mental comorbidity at any stage of their life.

The bidirectional relationship between anxiety, depression, and functional GI conditions is well illustrated by the largest longitudinal population-based study to date (Koloski et al., 2012). Individuals with higher levels of anxiety or depression at baseline were more likely to develop IBS, and baseline depression was predictive of subsequent dyspepsia by the 12-year follow-up. Among individuals without elevated levels of anxiety and depression at baseline, those with a functional GI condition at baseline had significantly higher levels of anxiety and depression at follow-up.

Stress is currently viewed as a risk or triggering factor for the onset of IBS and nonulcer dyspepsia, with studies showing higher levels of stress in the months preceding onset. Stress has also been established as a contributor to ongoing symptoms (Drossman et al., 2002). In fact, individual stress-sensitivity appears to be a key factor in the severity and persistence of functional GI symptoms. People reporting these gut symptoms have been found to exhibit exaggerated motor and sensory responses to stressors, including visceral hypersensitivity.

Similar to the research findings in IBD, very few studies have explored personality traits in patients with functional GI conditions. The available ones reviewed by Romanian researchers (Surdea-Blaga et al., 2012) have found higher levels of neuroticism for patients with nonulcer dyspepsia and IBS, compared to healthy controls, with some also reporting higher levels of conscientiousness and alexithymia in IBS. The IBS patients were also found to have higher neuroticism levels than IBD patients. However, it should be noted that neuroticism is a trait which is very susceptible to state influences and has been commonly reported as elevated in many chronic conditions; thus it is unclear whether it should be considered a precursor or a consequence of the chronic illness.

Psychological Therapies in GI Disorders

The close relationship between the brain and the gut via the brain–gut axis, the high prevalence of mental comorbidity in GI disease, and the evident impact of psychological processes on GI symptoms, disease course, and overall quality of life all support that psychological health should be a clinical consideration in GI disease management. Psychological therapies have been used as part of the treatment approach for several of the GI diseases. These psychosocial interventions have been more extensively examined in the functional illnesses such as IBS and nonulcer dyspepsia, but the efficacy of various therapy approaches has also been investigated in IBD. Psychotherapy, and in particular, cognitive behavioral therapy (CBT), a type of psychological therapy that uses an active, time-limited, and structured approach, has been well-established as an effective treatment for depression and anxiety, and in that regard it can be an appropriate intervention for mental disorders in GI patients. However, psychological therapies also aim to enhance coping, decrease stress reactivity, and address problematic behaviors (e.g., medication nonadherence, poor health habits), which in turn may have a positive impact on GI disease outcomes. While psychological therapies can affect GI and immune functioning, there is some question about whether they directly improve GI symptoms and disease course, depending on which GI illness is being reviewed.

There has been growing interest in the efficacy of psychological interventions for organic GI disorders, in part because of the positive results for functional GI disorders (described below). Interventions that have been evaluated for IBD using randomized controlled trials have included stress management, CBT, psychodynamic therapy, and most recently, hypnotherapy, with outcomes relating to psychological functioning and impact on IBD symptoms and course. There have been several systematic reviews, with mixed conclusions, in part related to differing decisions on inclusion criteria and study groupings. Most reviews included any psychotherapy-type intervention, rather than considering only psychological therapies with empirical support for efficacy in the general psychotherapy literature. One meta-analysis of psychological interventions in IBD (Timmer et al., 2011) concluded that there was no significant impact on emotional problems or disease activity. However, this review pooled theoretically different approaches with potentially differing efficacy, thus decreasing the likelihood of demonstrating an effect.

Overall, there is some consensus that the empirically supported treatments such as CBT and stress management (based on CBT strategies) have more consistently demonstrated improvements in HRQOL for IBD patients as well as in the targeted comorbid depression and anxiety (Knowles et al., 2013). In contrast, there have been few positive findings of impact directly on IBD outcomes, although many studies included only patients in remission, contributing to potential floor effects. One well-designed large case–control study found decreased medication use, decreased physician visits, and fewer disease relapses following psychological treatment (Wahed et al., 2010). Also treatment studies using hypnotherapy reported reduction in IBD symptom severity. The hypnotherapy results should be considered promising but preliminary, given that they were based on a small number of patients who received treatment. Methodological issues need to be more systematically addressed to better ascertain efficacy for the disease outcomes in particular.

The research on psychotherapeutic interventions for functional GI disorders has significantly expanded over the last decade. Studies have evaluated multiple therapy modalities, including brief psychodynamic therapy, hypnotherapy, relaxation training, and CBT. Psychological treatments, as a class of

interventions, have been found to be effective in reducing symptoms in IBS, compared to pooled outcomes for controls (Lackner et al., 2004). CBT has been shown to have a direct effect on IBS symptoms independent of its effects on psychological distress. A systematic review and meta-analysis of IBS outcomes and psychological therapies, which accessed data for almost 1300 adult patients in randomized controlled trials, also concluded that psychological therapies were effective for IBS (numbers needed to treat = 4; Ford et al., 2009). A similar review of pediatric studies reached a parallel conclusion, describing that psychological interventions with multiple therapy components (e.g., relaxation, psycho-education, cognitive therapy) were superior to standard care for outcomes of pain and functioning (Brent et al., 2009). While much of the research has focused on IBS, psychotherapy studies assessing outcomes for nonulcer dyspepsia have almost uniformly reported significant improvements in symptoms posttreatment, and benefits have been found to last up to 1 year (Soo et al., 2005).

All these reviews acknowledge study limitations, which qualify the strength of the conclusions, reflecting common challenges in many psychotherapy studies such as small sample size and difficulty blinding to treatment allocation. Nevertheless, treatment guidelines for IBS include psychological therapies as recommended interventions, particularly emphasizing CBT, psychodynamic interpersonal therapy, and hypnosis. New directions for psychological intervention with IBS have explored interoceptive exposure to gut sensations, mindfulness, and minimal contact treatments such as Internet delivery of CBT interventions, with promising results.

Studies that directly compared behavioral therapies with antidepressant medication for functional disorders (Drossman et al., 2003) have reported a better response to the psychological interventions and lower dropout rates, the latter suggesting a greater tolerance for the psychological versus pharmacological therapy. Psychotherapy was also found to result in significantly lower health care costs than medication or usual treatment approaches, highlighting an important cost-offset of psychotherapy.

Many, but certainly not all, patients are receptive to psychological care as part of the GI disease management plan. Inclusion of a psychological therapy can depend on availability of the treatment, and is often recommended depending on symptom severity, evident maladaptive coping, patient awareness of a stress–symptom connection, and patient readiness to engage in this type of treatment. While GI specialty clinics in many countries have adopted a biopsychosocial approach in their disease management, this approach is not yet a standard or common practice.

Conclusion

The interconnection of psychological and GI functioning is evident in both organic and functional GI disorders, supporting the applicability of a biopsychosocial model for these chronic conditions. The relationship seems to be bidirectional, with each able to affect the other, although the etiological role of psychological distress in GI disease such as IBD remains to be elucidated. The findings from both animal and human studies in this area have contributed to new understandings of biological underpinnings in psychological processes. These interrelationships have opened up further directions for treatment of GI disorders, with positive findings from psychological interventions related to improvement of patient outcomes and reduction of health care utilization. Nevertheless, more rigorous treatment studies are needed to determine patients most apt to benefit, efficient modalities for treatment delivery, and protective effects for disease course. Continued research efforts regarding the role of stress and preexisting depression, particularly in inflammatory disease, are likely to increase the understanding of the mechanisms linking the psyche and GI disease, and perhaps will facilitate more widespread integration of biopsychosocial treatment in gastroenterology.

Gated Communities

Renaud Le Goix, University Paris 1 Panthéon-Sorbonne, UMR Géographie-cités, Paris, France

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Gated communities are enclosed residential subdivisions, privately operated under contractual agreements between homeowners, yielding an interlocking of access control, legal arrangements, and social interactions. Built as morphological enclaves with physical enclosures and security features, they are also designed to exclude others: property rights are implemented in property owners associations, the private governance structures regulating the selection of residents based on age, lifestyle, or social preferences. Gated neighborhoods are therefore viewed as securitization strategies for the subset of the public who seek comfort in social homogeneity.

'Gated communities' (GCs) is a euphemism. Gated estates are a subset of a wider genre of enclave-style developments, better defined as privately governed and securitized neighborhoods. GCs are residential schemes organizing the governance and social structure with an interlocking of spatial, legal, and social systems.

Predominantly spatial and morphological analyses usually view GCs as simply walled and gated residential neighborhoods. Security systems, gates, and around-the-clock surveillance mean that gating blocks public access (Blakely and Snyder, 1997). GCs therefore represent a form of urbanism where public space has been privatized: they differ from condominiums and secured apartment complexes because behind the gates they include shared areas and amenities that are elsewhere open to the public and part of the urban common grounds (streets, parks, sidewalks, playgrounds, etc.). There has since been wide consensus to describe the security logic as a nonnegotiable requirement in contemporary urbanism and architecture. Many agree that both the privatization of public space and the fortification of urban realm, in response to the fear of crime, have contributed significantly to spatial and social diffusion of the phenomenon in different national contexts (Bagaeen and Uduku, 2010).

But legally speaking, all forms of residential enclosures also rely on property rights arrangements, implemented in property owners associations (POAs) and private governance structures that are designed to exclude others (common interest developments (CIDs)). These governing bodies are formed from among residents tied to a common set of interests by contract (Kennedy, 1995; McKenzie, 2006b, 1994; Owens, 1997), and there has been a variety of them used in different local contexts. GCs and walled neighborhoods are therefore a family member of a more general class that includes master-planned communities (horizontal version) and condominiums (vertical version) governed by collective tenure and incorporated organizational arrangements (Glasze, 2005). Important considerations from this perspective include the nature of ownership, governance, and management and how it interacts with local bodies of governments and communities (Kennedy, 1995; Le Goix, 2006).

That is to say that GCs rely on securitization forms that are embedding social strategies to seek 'comfort' and social homogeneity (Low, 2003; Gordon, 2004; Kirby, 2008), with a special focus on the impact of GCs on crime, segregation, property values, citizenship, and related behavior.

Mass Growth of Private Urban Governments

In almost two decades of academic debate on GCs, the different versions of GCs have been analyzed usually elaborating on the same language that describes privatized neighborhoods, but gating a neighborhood accentuates the societal impact. Their rise was initially fastest in the United States and Latin America, where the media and academic commentators were quick to describe the phenomenon in terms of security-oriented privatized urbanism. A popular critique easily followed, warning of the social fragmentation of the city, out-of-control urban segregation, secession, and the end of civic order as we know it. GCs became for some both symbols and symptoms of a line that is being crossed from voice-based citizenship to exit-based citizenship (Tiebout, 1956; Foldvary, 1994), from politically organized to market-organized civic society.

The Diffusion of Gated Communities in Different Contexts

Commentators have recorded the phenomenon across national contexts, under a diversity of denominations, all with contextual references and an emphasis on historical patterns of enclosures (Low, 2006; Bagaeen and Uduku, 2010): in Western Europe (Le Goix and Callen, 2010; Blandy, 2006; Raposo, 2006), in postcommunist Europe (Stoyanov and Frantz, 2006; Blinnikov et al., 2006; Cséfalvay, 2009), in the Arabian peninsula (Glasze and Alkhayyal, 2002), in Israël (Rosen and Razin, 2009), in China (Webster et al., 2006; Wu, 2005), in Southeast Asia and Australia (Kenna and Dunn, 2009), etc. Main motives have been identified, mainly hypothetical (Kenna and Dunn, 2009), although recent researches bring new empirical results (Cséfalvay and Webster, 2012). A first strong thesis implies that crime drives the market, linking security and fear of others – sometimes distinguished from the desire for security of person and

property. This strong linkage between the segregation of the affluent and their fear of crime has been thoroughly discussed in Latin America (Carvalho et al., 1997; Caldeira, 2000; Thuillier, 2005) and in South Africa (Landman, 2006), more than in other contexts. Gating has often been associated with both fear and a lack of confidence in the public security enforcement. A second hypothesis has focused on how residential preferences and economic rationale prevail, and GCs are therefore understood as an exit-option from the public realm, from the overregulated and overcrowded cities, inefficient in providing community service, in a 'gating growth machine (Vesselinov, 2008)'. Indeed, the main task of private urban governance is to privately organize and regulate the allocation of land and the local planning decision making (McKenzie, 1994), rather than a radical privatization of public goods as initially suggested by Blakely and Snyder (1997). As in the United States or in Latin America, contenders of the 'secession of the successful' tend to link GCs with inequalities and fear of others, and public defiance against the State. Figure 1 shows that GCs might be found in different contexts, and are as likely to be found in countries with lower level of inequalities and higher level of taxations, as in other countries. In Europe, however, an analysis of gating trends in several countries shows that driving factors (fear or crime, secession of the successful, and flight from blight) play different roles, and some other factors such as the political local attitude against centralization might also play a role. Indeed, in Europe, GCs are more common in countries with a lower economic level, highly centralized financing of local governments, higher social inequalities, and moderate redistribution of wealth (Cséfalvay and Webster, 2012). Gating in different local contexts is undoubtedly influenced in many ways by global models but it has also developed according to local political, legal, and architectural traditions, and national and local contexts prevails in analyzing the reasons why GCs are a common feature or exception, as in the cases of the Netherlands, Finland, or Germany.

Gates and Walls for Security

GCs have been described as a physical expression of post-industrial social changes (fragmentation, individualism, and rise of communities). Accordingly, they have been viewed as representing a deep penetration in society of the ideologies of fear and security – ideologies developed by dominant economic and political actors including municipalities and the homebuilding and security industries (Marcuse, 1995).

Figure 1 Countries with gated communities by Gini Index (2010*) and State Taxation Revenue (% GDP) (2010*).
Note: Triangle = countries with gated communities according to author's survey of academic literature; blank circles = countries without gated communities. AUS, Australia; BEL, Belgium; BGR, Bulgaria; BLR, Belarus; BRA, Brazil; CAN, Canada; CHL, Chile; CHN, China; CIV, Cote d'Ivoire; CZE, Czech Republic; DNK, Denmark; ESP, Spain; FRA, France; GBR, United Kingdom; GHA, Ghana; HUN, Hungary; IDN, Indonesia; IND, India; ISR, Israel; JOR, Jordan; KEN, Kenya; LTU, Lithuania; LVA, Latvia; NZL, New Zealand; PER, Peru; POL, Poland; PRT, Portugal; QAT, Qatar; ROU, Romania; RUS, Russian Federation; SGP, Singapore; THA, Thailand; TUR, Turkey; UKR, Ukraine; USA, United States; ZAF, South Africa. *Data as in 2010. For some countries, earlier reference data have been used (post. 2005). Sources: Author personal survey, 2012; World Bank, 2012; CIA, 2012.

The security argument drives a noticeable consensus among authors. Security features and guarded booths are a level of neighborhood security above the self-defensive 'armed response' placards posted on lawns, community programs of 'neighborhood watch' and community policing, and defensible space design approaches (Newman, 1972). At a more fundamental level, neighborhood gates simply extend the idea of the front door. An early theorization of gated streets as defensible spaces was developed by Newman and his Institute for Community Design Analysis. His studies have been widely publicized and incorporated in public policies through urban design guidelines aimed at preventing crime, which make an apology for gating as a device that prevents urban decay by giving social control over the environment to residents. This includes the erection of street barriers in retrofitted residential neighborhoods as a way of reintroducing public safety and controlling gang activities.

If there is a general understanding that GCs are places where the potential gain for stealing is higher than in other neighborhoods, empirical studies relating the erection of gates and crime are scarce. In fact, GCs frequently contribute to a relative decrease in burglaries and larcenies (Atlas and Leblanc, 1994), but also divert crime to other nongated communities in the close vicinity (Helsley and Strange, 1999). This diversion of crime often leads to a contagion of street barriers and security measures in neighborhoods close to GCs. In some places (Los Angeles and Mexico, for instance) cases of carjacking of GCs residents outside of the walls have also been reported.

While acknowledging that there are undoubtedly processes of market extension and cultural exportation going on, some authors have also stressed the local specificity of gated developments in specific national contexts and the importance of local emergence (Webster and Glasze, 2006). For example, Latin America has a rich history and modern culture in gating (Thuillier, 2005). Many appeared in the 1970s as a middle- and upper-income exodus to suburban areas where lower income groups had been settling since the 1940s. In those circumstances, gates were used to maintain a physical separation between classes when physical distances between rich and poor are short (Carvalho et al., 1997). Exploring the dual idea of spread and emergence in Lebanon, Glasze notes the similarity between some gated compounds and American developments, and also describes the links between US developments and Lebanese investors (Glasze and Alkhayyal, 2002) during the insecurity of the civil war and was for many a necessity in the face of public government not being able to provide personal and property security. The domination of the gated genre in South Africa clearly has very specific local causes. It has been linked to postapartheid postures, unilaterally by residents (Durington, 2006), by developers, or by more complex coalitions of local actors (developers and municipalities). The spread of enclosed enclaves (street closures and walls) is not only due to developers but also due to a strategy coordinated by local and national authorities and by very proactive residents associations. This has given rise to the extraordinary phenomenon of mass road closures, in which streets belonging to public governments are unilaterally enclosed by a boom gate and guard house and the enclave permitted to incorporate as an owners association ('Section 21 Company') (Landman, 2006).

Landscapes of Walls: An Historical Perspective

Gated cities have a long history. Socially and physically defined urban enclaves are as old as cities themselves. Private urban governance emerged in nineteenth-century industrial European cities such as London and Paris, where the new industrial bourgeoisie sought in privately operated and enclosed suburban neighborhoods, a quiet retreat from the busy city center. Le Parc de Montretout, in Saint-Cloud, France, developed in 1832, was probably the first of its kind (Le Goix and Callen, 2010). In the United States, the spread of GCs has roots in that country's long-standing ideology of suburban development, exclusionary zoning, and redlining (Ihlanfeldt, 2004; Kato, 2006). One early thread of influence is the romantic suburban utopias and utopian-influenced projects. Haskell's Llewellyn Park was probably the first modern GC built in the United States. It has continuously operated a gatehouse and a private police force since 1854 and introduced private governance of shared amenities based on deed restrictive covenants that protected the stability and homogeneity of the neighborhood. A second thread links America's modern GCs to the historical processes that brought CIDs and exclusionary restrictive covenants laws from Europe to the United States. McKenzie (1994) explores the long European history of restrictive covenants and residential associations (observable since 1743 in London). The first homeowners association (HOA) per se was created in the United States in 1844 in Boston's Louisburg Square. Llewellyn Park and Roland Park (1891) were the first large privately owned and operated luxury subdivisions, yielding exclusive neighborhoods. They established consumer and real estate developer expectations and legal and organizational approaches that helped shape contemporary private urban governance in the United States. In the first half of the twentieth century, this kind of high-end subdivision became quite common (Mission Hills, Missouri, in 1914; Kansas City Country Club District in 1930s; and Radburn in 1928). Along with landscaping and architectural requirements, the idea of social preferences as a commoditized attribute has become common in CIDs. Exclusive lifestyle developments became common by the turn of the 1960–70s, designed as mass-consumption real estate developments, financed by large corporations attracted by potential profits and backed by the Government through the Department of Housing and Urban Development.

Historical investigation of gated enclaves has produced a rich international comparative analysis that reveals the importance of local focus on the condition of appearance of gated developments. In China, GCs are nothing new, but simply a continuation of enclosed work-unit territories and the walled low-rise courtyard houses and residential neighborhoods found traditionally in villages and urban neighborhoods (Wu, 2005). In fact, China's strong control over land and housing has enabled municipal governments to engineer a faster rate of retreat to private (collective) territorial

government than has been possible in any other country. This is partly because of the strong legacy of collective organization left by the central-planning era.

Living by Contract

The economic theory of clubs (Buchanan, 1965) challenges the neoclassical notion of public goods. A club, in economics, is a method of supplying jointly consumed goods efficiently on the basis of controlled membership and fee. GCs can therefore be understood to be territorial clubs, the sole purpose of which is to supply club goods (Webster, 2002). This line of argument sees GCs as neither public nor private spaces. They are club spaces – spaces governed by 'small publics.' Compared to general purpose municipal governments, they are alleged to be more efficient organizations for allocating scarce resources for a number of reasons. They provide greater choice for one thing, and residents can vote with their feet to choose the bundle of shared goods and services they prefer at a given price. This leads to a comparison between the club community market and the imaginary spatial economy of geographical economist Charles Tiebout (1956). This is more efficient than public government in the sense that there are fewer unrealized gains from trade in the urban land market. In other words, more people have their specific preferences (for civic goods and services and for type of neighbor and neighborhood) met (Tiebout, 1956). The exclusionary mechanism of 'membership' means that there is a more precise relationship between payment and benefit received than there is in publicly managed neighborhoods. Significant investments made by POAs are capitalized in land rent. Not only do owners have an incentive to invest in their local environments, but also they can recover investment costs from rents (Foldvary, 1994). The sustainability is ensured by the existence of the HOA, which has three basic characteristics. Elected boards act as neighborhood decision makers, contracts govern resident behavior (through covenants, conditions, and restrictions), and monthly fees finance local amenities and services. By interpreting GCs as mechanisms for supplying environments, security, and other goods and services that are neither private nor public goods, the club economy model allows a more nuanced and specific debate about the roles of markets and governments in shaping, governing, and managing the city.

Regardless of local traditions and national legal contexts, there are different organizational types of private residential neighborhoods, differentiated by the way property rights are assigned, over-shared spaces, facilities, and exclusively used housing units: condominiums, stock cooperatives, corporations, and HOAs (Glasze, 2005). In *condominiums*, in addition to individual property of the housing units, the owners hold title to an undivided interest in the common property of streets, open spaces, amenities, and so on. The shared interest assets are governed by a POA run by an elected board of directors. In *stock cooperatives*, individuals purchase a share in an entire residential complex, but the co-op owns both the exclusively owned housing units and the subsequent shared amenities. The share gives the member voting rights at the co-op assembly. In *corporations*, the common spaces and facilities are the property of an incorporated body set up specifically for that purpose – the corporation or the HOA. A covenant is typically attached to the deed, making the owner a shareholder.

As of today, there has not been any empirical study making it possible to analyze the quantitative diffusion of gated developments in countries and cities. Some insights have been available in the United States, where by the year 2000 over 15% of the housing stock was in CIDs – and the number of units in these privately governed residential schemes rose from 701 000 in 1970 to 16.3 million in 1998 (McKenzie, 2006a). The Community Association of America estimated in 2002 that 47 million Americans were living in 231 000 community associations and that 50% of all new homes in major cities belonged to community associations (Sanchez and Lang, 2005). Only a proportion – varying from 12% to 30% in the region of Los Angeles (Le Goix, 2005) – of these private local government areas are also gated. Roughly 200 gated subdivisions in France and more than a 100 in the United Kingdom have been reported (Cséfalvay and Webster, 2012). But their spatial diffusion is also very much related to metropolitanization processes, and they are more commonly found in larger metropolitan areas, and more specifically in areas of faster growth within metropolitan areas, nearby innovative industrial clusters and newly developed urban edges. GCs are not specifically linked to wealthier categories of owners. In the United States and Europe at least, their diffusion to the middle class and upper middle class has been a turning point of the last 20 years, with products targeting specific public, such as Hispanics or Asian in US suburban areas, or niche markets based on lifestyle preferences (not only golf clubs, but also GCs with a private shooting range, or a private runway for general aviation home and plane owners).

The reshaping of metropolitan areas into cities of clubs can raise the total amount of revenue going into the management of the urban environment since people are clearly willing to submit to a double taxation regime (municipal government taxes plus GC fees). The flip side of this is that local governments can save money by off-loading responsibilities to HOAs. Seen in this light, the search for security is only a very partial explanation of the spread of GCs. Gated neighborhoods have given prospective buyers greater choice, lower risk, lower search costs, and greater investment security. They have also enabled public authorities to manage growth with greater fiscal sustainability. In fact, a strong hypothesis is that gating is highly correlated with the fiscal gaps increasingly experienced by local government bodies worldwide, and some empirical findings converge in Europe (Cséfalvay and Webster, 2012) or in the United States (Le Goix, 2006). Indeed, the diffusion of GCs in a metropolitan area is often related to suburban growth, in many countries an endemic antifiscal posture leading to municipal fragmentation and a Tibeoutian world of small competitive local governments. Urban sprawl in the United States and in many developing countries continues to generate demand for new infrastructure but political, legal, and technological limits on the amount of property tax that can be collected lead to undersupply. As a result, GCs, which bring wealthy taxpayers at minimal cost, have become the perfect cash cow for local municipalities.

Social Homogeneity, Property Prices, and Segregation

GCs are territories of exclusiveness, building up by design social homogeneity on security, snob values, fear of crimes, and symbolic and physical distance from others. But all these attributes are not truly independent, as they derive from the contractual agreement binding all property owners. Questions raised about their alleged effects usually address their efficiency on preservation of the tidiness and value of the neighborhood, and ultimately on segregation patterns.

Generally speaking, ownership in proprietary neighborhoods also encourages a kind of speculation around real estate prices. But gating such neighborhoods reinforces the proactive private governance effort toward property values preservation. The liberal hypothesis assumes that operating costs of private governance are paid for by the increase in property values.

First, the quasi-governmental regime previously discussed has a preeminent role in shielding property values. The short-term apparent cost-benefits market efficiency in providing collective services must be matched up to the risks of long-term spillover effects, inefficiency of the decision-making process, residents' lack of involvement, and the risks of obsolescence and inflating maintenance costs undermining the tidiness and reputation of a neighborhood and ultimately its property values. Many court cases and legal restrictions apply only to GCs and make a special case of their governmental regime, which cannot be extended to nongated private neighborhoods (Brower, 1992; Kennedy, 1995). At last, as public dedication cannot be obviously applied to gated streets, GCs need to live up to their promise and to be founded on a financial model that takes account of the rising costs due to the obsolescence of infrastructure and amenities managed behind the gates by the POAs. Gating a CID ultimately stresses the private realm, thus reinforces the selection of residents. This effort toward social control and homogeneity contributes to the overall effort of shielding property values and creating a price premium.

There are multiple and concurring evidences, based on diverse methodologies, of the price premium of GCs over nongated private neighborhood. On average, GCs are known to generate a price premium, and to better guaranty the homogeneity of property values within the neighborhood and to better protect values on the long run than other nongated private neighborhoods in the United States (Bible and Hsieh, 2001; Le Goix and Vesselinov, 2012). But the same studies also suggest that failure of POAs occurs when costs are rising above a sustainable level compared to rapidly decreasing property values. In principle, this is addressed by government legislation requiring adequate reinvestment funds, but there will undoubtedly be many failures in many countries before legislation has its effect. Some legislative adjustments of this sort already occurred in France in the 1920s, after numerous blue-collar and often-fenced private streets experienced rapid obsolescence and lack of maintenance detrimental to property values.

As mentioned earlier, private governance leads to an implicit selection of the owners. The effect of GCs on social homogeneity (Le Goix, 2005; Vesselinov et al., 2007; Wu, 2005) has been well established. Social homogeneity is achieved through design guidelines, age restrictions, or a selective club membership, and yields a measurable effect on local segregation: in the United States, GCs tend to segregate more by age (life cycle and age polarization) and by socioethnic status (White vs. Hispanics, correlated with wealth and age), and do not locally influence segregation patterns in terms of racial segregation (Table 1). On the other side of the spectrum, the integrative effects of GCs have also been emphasized, but it is all a matter of scale. A high-income GC has been built next to a long-established poor squatter community on the outskirts of Santiago, Chile, and lower income residents welcomed their new neighbors as sources of employment and utilities (water

Table 1 Social distance indices in southwestern metropolitan areas in the United States in 2010

	Principal components of socioeconomic segregation			
Metropolitan areas	*White vs. Hispanic status, correlated with wealth and age*	*Life cycle and ownership status*	*Life cycle and age polarization*	*Racial segregation*
Las Vegas, NV	1.3	1.4	1.6	0.8
Los Angeles – Long Beach, CA	1.4	1.4	3.1	1.5
Oakland, CA	1.3	1.1	3.6	0.8
Orange County, CA	1.2	1.5	3.0	1.2
Phoenix, AZ	1.6	1.0	3.0	1.5
Riverside – San Bernardino, CA	2.4	1.3	2.8	1.3
San Diego, CA	1.4	1.4	3.3	0.7
San Francisco, CA	1.7	1.8	1.5	4.1
San Jose, CA	1.0	1.0	0.9	1.3
Santa Cruz – Watsonville, CA	1.5	1.6	1.6	1.5
Ventura, CA	1.8	2.2	7.7	1.3

Note: Values indicated measure a normalized social distance (Social Distance Index (SDI)) between a gated community area and adjacent nongated neighborhoods, based on US Census geography (block groups) and factor analysis of social, economic, and racial variables.
For instance, on factor 1, the SDI between gated communities and abutting neighborhoods is 2.4 higher than between two adjacent nongated neighborhoods.
Methodology: Le Goix, R., 2005. Gated communities: sprawl and social segregation in Southern California. Housing Studies 20, 323–343.
Le Goix, R., Vesselinov, E., 2012. Inequality Shaping Processes and Gated Communities in US Western Metropolitan Areas, in: American Association of Geographers Annual Meeting - AAGs 2012. New York, NY (February 2012).

and sewerage) (Salcedo and Torres, 2004). The interesting question posed when new social geographies are established through GC-based gentrification – and the challenge to established understanding of segregation – is how well GCs and surrounding neighborhoods, especially of lower income, become functionally integrated and how this changes intergroup attitudes and wider complex systemic effects.

Gatekeepers in Social Science

Barbara Hoenig, Innsbruck University, Innsbruck, Austria

Abstract

A gatekeeper is an individual or collective actor who is in a position to control access to resources and rewards relevant in a particular social system. The term's usage in the sociology of science goes back to Robert K. Merton, who defines gatekeeping as one of the four complementary roles in the role set of scientists and scholars. Gate-keeping activities are relevant in different arenas of scholarship such as between scientific masters and apprentices, in collective mentoring programs, in publishing and in research funding.

A gatekeeper is an individual or collective actor who is in a position to control access to resources and regulate the allocation of rewards relevant in a particular social system. These resources might take the form of money or information, of reputation or social capital. In bureaucratic institutions, both formal and informal authorities can exercise a gate-keeping function. In the social institution of science, the normative role of a gatekeeper typically is twofold: "providing or denying access to opportunities" (Merton, 1973: p. 522), which includes giving advice, encouragement, and support on the one hand, and exercising control, regulation, and sanctions on the other. The concept of the gatekeeper has been introduced by Lewin (1943), who has investigated the food habits of five groups of Americans by tracing back various channels of buying and gardening, baking and canning food. Subsequent inquiries of gatekeeping have been most influential in communication research and in science and technology studies. In a panel study on voter decisions during a US presidential election campaign in Erie County, Ohio, Lazarsfeld et al. (1944) have investigated the hypothesis that mass media's influence on potential voters typically takes on a two-step flow of communication, insofar "ideas often flow from radio and print to opinion leaders and from them to the less active sections of the population" (Lazarsfeld et al., 1944: p. 151). In network analysis, recent research focuses on gatekeeping as a 'structural power condition' in order to discover structures that favor gatekeeping (for instance, Corra and Willer, 2002). In science, the gate-keeping role is important for institutionalized procedures of communication and decision making. Moreover, it contributes to the maintenance of scientific standards, evaluation, and quality assurance. Its institutionally central role has also stimulated research scrutinizing possible particularistic biases in decision making within a generally universalistic peer-review system (Zuckerman and Merton, 1971). Support and gate-keeping activities are relevant in different arenas of scholarship, as in the social ties between scientific masters and apprentices and in collective mentoring programs by affirmative action. It also bears upon the work done by journal editors in the publishing industry, by reviewers and foundation officers in research funding, and by departmental chairs and boards in career promotion of scientists and scholars. Apart from individual actors, institutions such as peer-review panels, funding organizations, scientific journals, and career track systems can take on a gate-keeping function in science and scholarship.

The Gatekeeper's Role in Science

The term's usage in the sociology of science goes back to its founding father, Robert K. Merton, who defines gatekeeping as one of the four complementary roles in the role set of scientists and scholars: Apart from teaching, research, and scientific administration, they are expected to fulfill a gate-keeping function in the institutionalized peer-review system (Zuckerman and Merton, 1972). Merton characterizes gate-keeping as "basic to the system of evaluation and the allocation of roles and resources in science" (Merton, 1973: p. 521), where gatekeepers mostly operate through panels of peers. Becoming a member in these panels is part of the scientific socialization, while gate-keeping activities "help shape the permanent record of scientific work" within "patterned sequences of role configurations" (Merton, 1973: p. 521). According to Merton, the gate-keeping role is clearly structured toward an older age bias, because scientists and scholars usually act as gatekeepers in later phases of their career, when their reputation as researcher in the field of question is already established or assumed. In dynamic aspects, the role of the gatekeeper effects the 'sponsored mobility' of scientists and scholars (Turner, 1960; Hargens and Hagstrom, 1967): In contrast to a mobility pattern similar to a sporting contest, where individual achievements are solely judged according to universal criteria, sponsored mobility involves a "controlled selection process" where members of the elite "*call* those individuals who have the appropriate qualities" (Turner, 1960: p. 857). The fact that, irrespective of their actual achievements, particular researchers and scientific institutions are structurally more successful than others in the cumulative process of accumulating reputation and reward is known as the 'Matthew effect' (Merton, 1968). Structurally seen, the gate-keeping role is crucial for understanding the operation of intellectual authority and the reproduction of social stratification and scientific elites (Cole and Cole, 1973; Zuckerman, 1977; Whitley et al., 2010). Gatekeepers control and regulate legitimate access to institutions as those intellectual authorities that define what counts as 'scientific excellence' or not. In this sense, gatekeeping has far reaching consequences on whether a particular person is allowed to continue research, be it on a particular topic or doing research at all. In the following, we take a look on different arenas of science as a social institution, where gate-keeping activities are involved: in the social ties of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03011-7

scientific masters and apprentices, in collective mentoring by affirmative action programs, in the publishing and research funding industry, and in sociocognitive networks or 'invisible colleges' in the scientific community.

Masters and Apprentices in Science

One of the most important, albeit highly personalized social ties in science, are those between the scientific master on the one hand and the apprentice on the other. Alternative terms often used to characterize this role relation are teacher–pupil, mentor–student, or senior–junior collaborators. In the process of scientific socialization-by-filiation, the master acts as teacher and supervisor, supporter and mentor, and as an individual role model for the apprentice. As Zuckerman and Merton (1972) have observed, complementary age roles of teachers and students that usually are members of different generations and cohorts often become integrated in research collaborations; the relation is also characterized by a remarkable amount of conflict and sociological ambivalence for both (Zuckerman and Merton, 1972). The mentor's relevance for the career prospect of any young scientist or scholar has also been an object of social research. For instance, Nobel laureates in interviews have frequently emphasized the important role of a reputed mentor for making a career within the scientific ultraelite (Zuckerman, 1977). In her study on Nobel laureates in the United States, Zuckerman has characterized these enduring, consequential social ties between scientific masters and apprentices as much more important than ties by kinship. More than half of the laureates in her sample have been working as graduate students, postdoctorates, or junior collaborators under older laureates or similar members of the ultraelite without Nobel prize (Zuckerman, 1977). Zuckerman has found a self-perpetuating pattern of the scientific ultraelite, where Nobel laureates, by acquiring experience and judgment and by acting as "skillful advocates of their candidates" (Zuckerman, 1977: p. 106), produced their own 'heirs to the prize' in a lineage sometimes stretching over half a century. As fundamental difference between biological and social heredity Zuckerman emphasizes the aspect of social choice in that relationship: At least to some extent, both masters and apprentices can mutually choose with whom they want to work. Moreover, it can be assumed that scientific masters possibly tend to prefer apprentices that are perceived to be similar to themselves at a younger age. Mostly informal, personalized patterns of recruitment and support, in the aggregate, then might favor structural majorities at the expense of 'minority' members in science.

Collective Mentoring by Affirmative Action

In the social stratification of science, the situation of women and other 'minorities' has always been rather peculiar. Irrespective of their actual individual achievements, they are more frequently working in organizational contexts disadvantageously affecting the cumulative allocation of reward during their scientific career. This bears upon appointments to institutions with low prestige, lacking eminent mentors, and access to scientific networks, publishing later and less than others, more seldom being held eligible for research funds and fellowships (Keith et al., 2002). This is one reason why members of these groups are much scarcer as gatekeepers of science as well and structurally encounter fewer opportunities to shape research policy issues. Respecting the normative ethos of universalism (Merton, 1942), which regards the validity of scientific knowledge claims as independent of irrelevant personal characteristics of scientists, often leads to support institutional measures for equal opportunities in science. In this sense, affirmative action for disadvantaged groups can be understood as a critique on a still lacking universalism in access to science.

Affirmative action designates institutional measures of support, for instance, by quotas, targets, and mentorship, in order to counteract individuals' exclusion from opportunities based on group membership such as by race, class, and gender. These institutionalized forms of support aim at integrating members of these groups in academic networks by mediating knowledge about scholarly practices and by generating opportunities for experiencing career support and collegiality. Moreover, by affirmative action it is expected to provide more equal access for 'minority' members to shaping research policy at all relevant levels. Within the last decades, there has been done much research on affirmative action in the educational and employment system (Harper and Reskin, 2005). However, experience shows that it very much depends on programs' actual implementation practices whether their outcomes really benefit 'minority' members or not (Aguirre, 2000). Both social disparities and institutional programs to combat discrimination in the academe significantly vary between countries; particularly Anglo-Saxon and European Scandinavian countries are perceived as more advanced in that regard. While in the United States, affirmative action in higher education has responded to the Civil Rights movement from the 1960s onward, European countries only recently have begun to learn from these experiences (Bacchi, 1996; Appelt and Jarosch, 2000). In 1997, the European Union has adopted a legal guideline for actively pursuing anti-discriminiation strategies as part of the 'Treaty of Amsterdam,' such as by implementing gender mainstreaming and strategies combating racism. Except for the United Kingdom (HESA, 2012), however, most European countries' higher education statistics do not provide information with respect to known ethnicity-status, which indicates that 'minority' issues still are not much on the science policy agenda there.

Gatekeeping in the Publishing Industry

The gatekeeper's role in science has mostly been investigated in fields of publishing, such as by research on journal or book editors or reviewers evaluating manuscripts submitted for publication. In science and technology studies, Price (1963) has coined the term 'invisible colleges' for informal groups of scientists and scholars that, by communicating, reading, and citing each other's work, contribute to scientific growth. While Price has estimated the size of such a scientific network as "a few hundred colleagues for every worker" (Price, 1963: p. 72), he has not explicitly addressed possible disciplinary differences in that

regard. Crane (1972) has built upon Price in her research on the role of invisible colleges in the diffusion of scientific knowledge and ideas. By bibliometrics and survey research, she investigated the social organization of informal collaboration networks among mathematicians and rural sociologists. In addition, she provided a dynamic model of scientific growth, both of scientific communities and their knowledge production. In an earlier study of comparing 50 journals from two disciplines, sociology and economics, Crane (1967) has scrutinized factors of the academic stratification system that highly affect editorial decisions in the selection of journal articles. She has found empirical evidence that an author's academic affiliation, doctoral origin, and professional age happened to be rather similar to the distribution of those characteristics among journal editors. Moreover, she suggested that these effects might be specific for each discipline. The publishing industry in an American context has been described by Coser, Kadushin, and Powell (Coser, 1965, 1975; Coser et al., 1982) as by three structural characteristics: its decentralization; its operating in a highly uncertain, unpredictable market; and its internal organization characterized by a predominance of craft over bureaucracy. According to the authors, decisions of publishers and editors are based on multiple factors such as estimations of prospective sales, but also on the tradition of a particular publishing house, the size of a firm, editors' previous education, career aspirations, and self-images. Moreover, they indicated that these points of reference at least partially depend on an editor's structural characteristics, to a less extent they are chosen at will. Since the turnover rate among editors is rather high, structurally induced uncertainty and ambiguity of that role are even enforced so that "the complicated network of particularistic relations between authors and editors runs counter to the universalistic contractual relations between the firm and its authors" (Coser, 1975: p. 19). As Price and others have shown, the scholarly communication between scientists through scientific papers goes back to the seventeenth century. However, despite their central role for scientific communication, social research on journals' editorial boards is still rather scarce. Recently, the role of gatekeepers in scholarly communication has been measured as interlocking editorial board membership, taking the number of editorial board members that two journals share as an indicator for the journals' proximity (Ni et al., 2013). For 58 journals from the disciplinary field of Library and Information Science, the authors could show that about 10% of editorial board members served on more than one journal. Their findings demonstrated a rather high concentration for this variable when compared with journal proximity in term of producers, scientific papers, and papers' topics (Ni et al., 2013). The approach of editorial board member coupling can generate interesting insights in networks of journal clusters within a given field or research area and in the structure of editorial gatekeeping as well.

Gatekeeping in Research Funding

Since the norm of universalism requires that the evaluation of scientific achievements is independent of individual attributes of any scientist (Merton, 1942), it is reasonable to ask whether the actual evaluation practice of peer reviewers reflects this norm. However, researchers studying the role of peer review in research funding have frequently emphasized that it is extremely hard to find any statistically significant evidence for particularistic effects. In addition, there might be no way of objectively evaluating new scientific work neither. Cole (1992) reported several empirical studies on peer review in the US National Science Foundation where the authors could not find statistically significant correlations of grant approval rates neither with individual characteristics of researchers nor with their institutional affiliations. Cole hinted to the fact that these findings not only contrast much theorizing in the field, but also those of qualitative studies and academic insiders' everyday-knowledge of what affects working at universities. Rather, he assumed that informal network ties can produce significant outcomes interpretable as Matthew effect, and he suggested to investigate them by applying social network analysis or qualitative research techniques. Lamont's (2009) qualitative study on scientific decision making has shown that external peer reviewers of funding programs in the United States practically apply some rules of thumb when talking about what constitutes a proposal's potential scientific excellence. Moreover, she unearthed significant variation in these 'customary rules of deliberation' (Lamont, 2009) across disciplinary cultures and corresponding epistemological styles in the social sciences and humanities.

Not only scientific actors, but also funding institutions and their representatives administering the granting process play an important gate-keeping role. Decisions consequential for grant approvals can be taken by individual philantrophs, science policy advisors, members of the scientific administrative elite, or by the program officer appointed to a research foundation. Although not acting as scientist, these actors often received academic training, which also equipped them with an insider-knowledge of the research field and with access to scientific networks. In the history of social scientific research funding, such as by the Rockefeller or by the Ford Foundation, professional foundation officers were often trained social scientists using their institutional position to promote social scientific research (Platt, 1996: pp. 164ff.). Therefore, a sharp distinction between foundation officers and researchers might be misleading, both because of the officers' scientific education and the multifold trajectory of their professional careers, occasionally moving back and forth between the administrative, the advisory, and the research sector (Platt, 1996: pp. 164ff.). At meso- and macrolevel, research foundations, state ministries, administrative elites, and employers' organizations can be conceived as gate-keeping agencies shaping the research policy of a country, for instance, by setting up academic evaluation systems or funding regulations operative in a national research landscape (Whitley et al., 2010). As Whitley and others have shown, different types of change in governance and state steering might then affect the reorganization of authority relations and innovation in public science systems as well.

Historical and Cultural Variation of the Gatekeeper's Role

Probably it is most hard to investigate the role of gatekeepers in career track decisions and scientific promotion, for instance

in the decision whether a scientist shall get tenure or not or whether a scholar shall be appointed for a prestigious professorship. Moreover, the gate-keeping role apparently is subject to historical change and cultural variation. For instance, concerning the historical chains between masters and apprentices in sociology, Merton and Riley (1980) have edited a small book in which eminent sociologists report about their teachers and their relation to them. When, as readers of today, we contrast their experiences with current conditions of doing research, we might recognize that paternalistic hierarchies of highly personalized, gendered, age-structured, and elitist roles at least partially have changed toward more entrepreneurial forms of science and scholarship. Structural transformations of public science have given rise to new actors and institutional forms of knowledge production, such as by industrial enterprises or science policy advisors. By extending beyond traditional boundaries of academic scholarship, the future role of gatekeepers might become more diverse and diffuse, possibly enforcing structural contradictions and ambivalences for scientists and scholars depending on these contexts of utilization. The cultural variance of the scientific role in different social contexts has been investigated by Ben-David (1971) who, inspired by Weber's and Merton's historical studies, observed successive shifts of scientific centers from England to France, then to Germany, and finally to the United States. While Ben-David has characterized the specific strength of French universities in their strongly centralized, elite-oriented system, this has been partially replaced by the Humboldt tradition of autonomous, hierarchical universities in Germany. Particularly after World War II, a steadily increasing number of independent universities in the United States with more democratically structured departments has established itself as a globally dominant academic system till today. Although Ben-David has not explicitly studied social variation in the gate-keeping role, his early studies demonstrated the context-dependent nature of knowledge production in different academic systems. Despite an increasingly globalized higher education system, the historical variance of academic institutions and national traditions of scholarship can be regarded as still of importance. The fact that the gatekeeper's role is subject to remarkable historical change and cultural diversity reminds us of the need to apply context-sensitive research techniques in empirically studying it.

Seen from the perspective of the sociology of science, the gatekeeper's role is of relevance for maintaining what is constitutive for scientific knowledge production: an institutionalized procedure of 'organized skepticism' (Merton, 1942) for assuring scientific quality standards, shaping the growing stock of knowledge, and contributing to scientific advance. Although by current science studies it is widely acknowledged that subjective judgments are an indispensable part of any evaluative activity in science (Polanyi, 1958), it remains an open question how and to which extent this is the case. The gatekeeper's role seems to be more important in counter-balancing subjective effects of scientific evaluations by implementing the norm of universalism in academic judgments. Even though the most universal evaluation systems in science might not always be the most efficient ones for advancing scientific knowledge, it can be assumed that "'Universalism' and 'Fairness' are 'good' ways to distribute rewards because they fit our general value system" (Cole, 1992: p. 203). The continuing relevance of the gatekeeper's role lies in the fact that it fundamentally forms both the procedures and outcomes of scientific knowledge production. In this sense, it contributes to what is constitutive for science as a social institution.

Gauss, Carl Friedrich (1777–1855)

Richard W Farebrother, Victoria University of Manchester, Manchester, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Carl Friedrich Gauss was born on 30 April 1777 in Brunswick (Germany) and died in Göttingen (Germany) on 23 February 1855. Gauss contributed to all areas of science known in his day, notably to astronomy, physics, and geodesy, but this article concentrates on his contributions to statistics and numerical methods. In 1805, Legendre published an algebraic procedure for the linear fitting problem that he named the method of least squares. Gauss's first (1809) statistical derivation of this procedure was based on a combination of the normal distribution with a Bayesian variant of the maximum likelihood optimality criterion. Later, Gauss (1823–28) gave a very full account of an alternative decision-theoretic approach, which employed the mean squared error of the estimator as optimality criterion. In particular, he identified the least squares estimator as the linear unbiased estimator of the parameters with minimum mean squared error. Gauss developed the Gaussian elimination technique for solving determinate systems of linear equations, and explained how nonlinear relationships may be fitted by means of an iterative variant of the method of least squares. He also developed a second iterative (relaxation) procedure related to the Gauss–Seidel procedure.

Introduction

The name of Gauss will already be known to many readers for its use in such phrases as Gaussian distribution, Gauss linear model, and the Gauss–Markov theorem, and for its use in the titles of the Gaussian elimination, Gauss–Jordan, Gauss–Doolittle, Gauss–Newton, and Gauss–Seidel procedures, if not for the *Système International* unit of magnetic induction and the associated terms Gaussage and degauss.

Gauss contributed to all areas of science known in his day, notably to astronomy, physics, and geodesy, but in this article we shall concentrate on his contributions to statistics and numerical methods. For more wide-ranging surveys of his work, see Eisenhart (1968) and May (1972).

Life of Gauss

Carl Friedrich Gauss (originally Johann Friedrich Carl Gauss) was born on 30 April 1777 in Brunswick (Germany). He was the son of a bricklayer and gardener who also kept the accounts of a local insurance company. Gauss received his elementary education at St. Katherine's School in Brunswick. However, his humble origins were not allowed to hamper his intellectual development, for, in 1791, his talent for mathematics was brought to the attention of Carl Wilhelm Ferdinand, Duke of Brunswick, who undertook to support his continuing education, at first at the *Collegium Carolinum* in Brunswick and later at the University of Göttingen (in the Hanoverian territory of King George III of Great Britain and Ireland). Gauss did not graduate from the University of Göttingen but was awarded a doctoral degree *in absentia* by the University of Helmstedt in 1799 for his work on the fundamental theorem of algebra.

In October 1806, the French land forces consolidated the command of German territory that they had established in 1805 in the battle of Austerlitz by defeating a Prussian army under the command of the Duke of Brunswick at Auerstedt (and mortally wounding the Duke). As a consequence, when in 1807 Gauss submitted the manuscript of his future *Theoria Motus Corporum Coelestium* for publication in German, the political situation was such that his publisher felt obliged to insist on its translation into Latin. Consequently, the manuscript that Gauss had completed in 1806 was not published until 1809. Fortunately, Gauss had an excellent command of Latin, so that this imposition may justly be compared with requiring a modern German scholar to translate his work into English before publication. On the other hand, Gauss and other German scholars continued to publish in Latin until the middle of the nineteenth century.

In 1807 Gauss was appointed director of the University of Göttingen observatory and professor of mathematics at the University of Göttingen. He continued to hold both of these positions until his death in Göttingen on 23 February 1855.

Elementary Fitting Procedures

Given any number of observations n on a lesser number q of variables, the linear fitting problem is concerned with establishing the linear relationship between one of these variables and the remaining $q - 1$ variables and a constant term. Before the middle of the eighteenth century, practitioners were obliged to employ a variety of more or less arbitrary procedures to determine the values of the parameters of such relationships. But between 1750 and 1800 four algebraic procedures were proposed for the linear fitting problem, namely the method of selected points which sets q of the deviations from the fitted relationship equal to zero; the method of averages which sets q simple linear combinations of the deviations equal to zero; the method of (constrained) least absolute deviations which chooses values for the parameters to minimize the sum of the absolute deviations subject to the condition that the signed deviations sum to zero; and the minimax absolute deviation procedure which chooses values for the parameters to minimize the largest absolute deviation.

By contrast with Laplace (*see* Laplace, Pierre-Simon, Marquis de (1749–1827)), who wrestled with various aspects

of the last three algebraic fitting procedures for more than 30 years (1786–1818), Gauss (1809) did not have much to say about any of them. He summarily rejected the method of selected points as the imposition of zero values on q of the deviations necessarily requires some of the remaining deviations to take larger absolute values than they need. Then, turning to the method of least absolute deviations, he defined the unconstrained variant of the problem (which Laplace subsequently named the method of situation) and characterized the solution of either variant of this fitting procedure by a set of zero deviations equal in number to the number of unknown constants minus the number of constraints. He also noted that once the set of zero deviations defining the optimal fit had been determined, the remaining observations had no influence on the values to be assigned to the unknown constants. Then, presumably recollecting his critical view of the method of selected points, he seems to have had nothing further to say about either variant of this procedure.

Method of Least Squares

In 1805 Adrien-Marie Legendre (1752–1833) published an alternative algebraic procedure, which he named the method of least squares. This procedure chooses values for the parameters of the relationship to minimize the sum of the squared deviations between the observed values and the fitted relationship. For a detailed history of the four algebraic procedures, of Section Elementary Fitting Procedures and the method of least squares, see Farebrother (1999). Also note that the relevant pages of Legendre's original statement have been reproduced by Stigler (1986: p. 56).

Legendre's approach to the fitting problem was entirely algebraic and had no statistical content. Further, he did not prove many of the optimality properties he claimed for the method of least squares. Indeed, he had not even shown that the values determined by setting the q first derivatives equal to zero actually minimize the sum of the squared deviations function (except in the unlikely case when the fitted relationship is exact). Such a proof was subsequently supplied by Gauss (1809). (Further, many readers will know that Legendre's solution represents a minimum of the sum of the squared deviations function as the corresponding $q \times q$ matrix of second derivatives is symmetric and positive definite.)

As recently as 2005, it was discovered that the portrait universally employed to illustrate articles about the mathematician Adrien-Marie Legendre was actually that of the butcher and revolutionary politician Louis Legendre (1752–97).

Normal Distribution

As a precursor to his first statistical derivation of the method of least squares, Gauss obtained the statistical distribution now known as the normal or Gaussian distribution from a preliminary analysis in which the arithmetic mean of a set of direct observations is associated with the maximum value of the Bayesian variant of the maximum likelihood or maximum probability optimality criterion.

Despite its obvious defect, Gauss's argument spawned a host of papers by various authors which were concerned with the derivation of the Principle of the Arithmetic Mean from simpler axioms; see Farebrother (1999) for details. In particular, in their textbook *The Calculus of Observations* (1924), Sir Edmund Taylor Whittaker (1878–1937) and G. Robinson showed that the arithmetic mean is the only twice differentiable function of the observations, which is equivariant to changes of location, equivariant to changes of scale, and invariant to permutations of the order of the observations.

Similarly, in his *A Treatise on Probability* (1921), Keynes (*see* Keynes, John Maynard (1883–1946)) used variants of Gauss's argument to identify continuous symmetric and nonsymmetric distributions associated with the arithmetic, geometric, and harmonic means and the median, and suggested that it is not possible to find such a distribution associated with the mode.

Most Probable Value Criterion

As noted above, Gauss's first statistical derivation of the method of least squares was based on a combination of the normal or Gaussian distribution with a Bayesian variant of the maximum likelihood or maximum probability optimality criterion. As Gauss was working in a Bayesian context, there was no need for him to estimate the disturbance variance, but he employed a simple algebraic procedure that we would now associate with the LDL′ decomposition of a symmetric matrix to obtain measures of relative precision of each of the parameter estimates.

Priority Disputes

In his 1809 book, Gauss referred to the method of least squares as 'our principle, which we have made use of since the year 1795' and thus sparked off a serious priority dispute with Legendre that ran on for several years. Although Legendre had certainly been the first to publish a description of the method of least squares, it is now generally agreed that Gauss had employed a similar procedure in his unpublished work, notably in his 1801 analysis of the geodetic measurements made in France, see Plackett (1972) and Stigler (1999: Chapter 17).

In this context, we should also mention that the (normal) probability distribution named for Gauss had previously been discussed by Abraham de Moivre (1667–1754) and Pierre-Simon Laplace (1749–1827) although neither of Gauss's predecessors seem to have considered the normal curve as a probability distribution in its own right; *see* Husserl, Edmund (1859–1938) and Stigler (1999: Chapters 14 and 22).

Following the rediscovery of his work in the 1870s, somewhat belated claims for priority were also made on behalf of the Irish-American Robert Adrain (1775–1843), who in 1809 had identified the normal distribution independently of Gauss (if not of Legendre) and applied the method of least squares to a variety of practical problems related to land surveying and dead reckoning at sea.

Asymptotic Results

In the main text of his *Théorie analytique des probabilités* of 1812, Laplace had made use of a nonrigorous asymptotic argument to establish the optimality of the method of least squares. Gauss (1816) employed a similar technique to establish the relative efficiency of the scaled sums of powers of the absolute disturbance terms when employed as estimates of the variance of their common distribution function. In particular, he found that the scaled sum of the squared disturbances is a more efficient estimator of the variance parameter than is the scaled sum of their absolute values and significantly better than the scaled sums of their third and higher powers.

The Most Plausible Value Criterion

In 1818–19 Gauss abandoned his earlier Bayesian derivation of the method of least squares and adopted an alternative approach, which he later published as Gauss (1823–1828) in three parts. Farebrother (1999) has suggested that the principal features of Gauss's second approach to the fitting problem may be traced to a careful recombination of certain elements in Laplace's earlier work. Gauss adopted Laplace's decision-theoretic approach to the fitting problem, and his restriction to what we would call a class of linear unbiased estimators, but employed finite sample theory rather than asymptotic analysis, and chose a value for the parameter to minimize the expected value of the squared error of estimation where Laplace had chosen to minimize its expected absolute value.

The principle result of this new theory, now known as the Gauss–Markov theorem, identifies the least squares estimator as the member of the class of linear unbiased estimators with minimum mean squared error (and thus minimum variance).

On the other hand, it came as something of a surprise to the present author to discover in 2002 that the result underlying the so-called Gauss–Markov theorem is algebraically identical to the result defining the method of least squares.

In this context, it is interesting to note that Gauss's restriction to the class of linear unbiased estimators was an accidental by-product of Laplace's earlier concern with estimators defined by the method of averages, see Stigler (1986) or Farebrother (1999). However, Gauss also showed that the scaled sum of squared deviations is an unbiased estimator of the disturbance variance, but without making any strong claims for the optimality of the result.

Updating Formulas and Recursive Residuals

Gauss (1823–1828) gave a very full account of his second approach to the subject. In particular, he extended his earlier analysis by considering the effect on the fitting problem of adding a further observation, or of imposing a linear constraint on the parameters of the model, see Plackett (1950). The resulting updating formulas now form the basis of the Kalman filter of times series analysis, see Farebrother (1990–1992).

In this connection, it is interesting to note that a particular use of Gauss's updating formulas results in a simple demonstration of Paul Anthony Samuelson's (1915–2009) formula for how deviant the square of a particular observation can be when expressed as a proportion of the sample variance.

The standard updating formulas also implicitly define the set of $n-q$ recursive residuals employed in some modern statistical tests.

Solution of Linear Equations I

The solution technique now known as Gaussian elimination is a development of the procedures known to Tobias Mayer (1723–62) and the ancient Chinese for solving systems of q linear equations in q unknowns. In his (1809) worked example, Gauss employed a solution technique, which may possibly be associated with the ancient method, see Farebrother (1999). But in 1811 Gauss outlined the steps of a solution technique that identify the elimination procedure which now goes by his name. This procedure has two phases: in the forward elimination phase the first equation is used to eliminate one of the unknown constants from the other $q-1$ equations; then the second equation is used to eliminate a second unknown constant from the remaining $q-2$ equations; and so on. This yields an upper triangular system of equations, which is then solved for the unknown constants in reverse order.

Gauss's early work in astronomy was concerned with the computation of the elements of the orbits of the asteroids Ceres and Pallas, which had been discovered in 1801 and 1803, respectively. It therefore comes as no surprise to find that Gauss (1811) illustrated his computational technique by a worked example concerned with the least squares determination of the six elements of the orbit of Pallas. (It is interesting to note in passing that the discovery of these asteroids is also remembered in the names cerium and palladium attached to the chemical elements with atomic numbers 58 and 46 discovered in the same years.)

In the standard elimination procedure, the elements of the upper triangular system are gradually adjusted until they take their final values. In 1881 Myrick Hascall Doolittle (1830–1913), a 'computer' at the US Coast and Geodetic Survey, published his account of a variant of Gauss's procedure in which all the calculations necessary to determine the final value of any given element of the upper triangular system are performed in a single operation. This slight adjustment of the standard computational procedure was extremely valuable in an era of pencil and paper computations and continues to be of value today when particularly accurate results are required, see Farebrother (1988).

Numerous minor variants of the Gauss–Doolittle procedure were proposed over the next 70 years, but it is perhaps fitting to single out that of Henry Agard Wallace (1888–1965) who independently proposed a method similar to Doolittle's in 1925, some 20 years before he served as US Vice-President in 1941–45.

Solution of Linear Equations II

The so-called Gauss–Jordan procedure differs from the original Gaussian elimination procedure in that each step of the forward elimination phase of the revised procedure eliminates

one of the unknown constants from all but one of the equations. Thus, the first equation is used to eliminate one of the unknown constants from all equations except the first; the second equation is used to eliminate a second unknown constant from all equations except the second; and so on until the original system of equations is reduced to diagonal form and this reduced system solved by simple division.

This minor modification of the standard elimination procedure will be familiar to many readers from textbook descriptions of the simplex procedure of linear programing. It leads to a considerable simplification of the second (back substitution) phase of the elimination procedure but usually at the cost of some loss of numerical accuracy, see Farebrother (1988) and Stewart (1995).

Matrix Algebra

As a by-product of his work in number theory and the calculus of observations, Gauss (1801, 1809, 1823–1828) made use of several concepts now recognized as belonging to the theory of matrices. These include linear dependence; linear transformations; the Lagrange LDL′ and Cholesky LL′ decompositions of a symmetric matrix; the rank-one adjustment of a symmetric matrix; the inverse of a triangular matrix; the inverse of a symmetric matrix; and, possibly, the generalized inverse of a matrix of full rank. He also explicitly proved that the inverse of a symmetric matrix is itself symmetric.

Moreover, in the *Premier Supplément* (1816) to his *Théorie analytique des probabilités*, Laplace employed from of the ideas implicit in the notation of Gauss's (1809, 1811) computational procedures to develop a prototype of the orthogonalization procedure which modern textbooks of numerical analysis identify as a 'modification' of the so-called classical Gram-Schmidt orthogonalization procedure first enunciated some 80 years after Laplace's death by Erhard Schmidt (1876–1959) in 1907. Farebrother (1988) has suggested that the current terminology may be simplified by naming these two orthogonalization procedures for Laplace and Schmidt, respectively.

Despite these early beginnings, the familiar matrix formulation of the least squares problem did not materialize until the 1930s, and it did not become a common feature of statistical textbooks until the second half of the twentieth century, see Plackett (1950) and Farebrother (1999). Indeed, the immediate reaction of two leading statisticians, Florence Nightingale David (1909–93) and Jerzy Neyman (*see* Neyman, Jerzy (1894–1981)), to a 1935 publication by Alexander Craig Aitken (1895–1967) was to reestablish the same result using the more familiar notation of determinants. Fortunately, the only permanent effect of this retrograde step was the superfluous addition of the name of Andrei Andreivich Markov (1856–1922) to that of Gauss in the conventional name of the Gauss–Markov theorem of Section The Most Plausible Value Criterion.

Iterative Fitting Procedures

Gauss (1809) also explained how nonlinear relationships may be fitted by means of an iterative variant of the method of least squares, now known as the Gauss–Newton procedure, in which the fitted relationship is linearized by a Taylor series expansion and fitted by the method of least squares. This process being repeated until a satisfactory level of convergence is obtained.

Despite its early origin, and the publication by Gauss of detailed worked examples in astronomy and geodesy, the Gauss–Newton procedure was not widely adopted for practical work in other areas until the necessary computing equipment became readily available in the second half of the twentieth century. Instead, practitioners avoided the computational burden imposed by the iterative procedure by transforming their nonlinear relationships to a linear or a more linear form before estimating the parameters of the resulting equations by a *single* application of the method of selected points, the method of averages, or the method of least squares.

Nor was the use of such preliminary transformations restricted to the work of applied scientists with little training in statistics as Hotelling (*see* Hotelling, Harold (1895–1973); Pearson, Karl (1857–1936)) among others employed variants of this method in their practical work. Indeed, as late as 1930, Henry Schultz (1893–1938) attempted to persuade his fellow practitioners to employ the 'true' method of least squares when fitting nonlinear statistical models as the alternative approximate procedures sacrificed variance to computational ease, see Farebrother (1998, 2006).

A second iterative procedure usually named for Gauss is the Gauss–Seidel procedure, although Gauss and Seidel were actually not concerned with the procedure that usually goes by this name, but with a distinct fitting procedure known as the method of relaxation, see Gauss (1823–1828) for details.

Concluding Remarks

The method of least squares and the related statistical procedures known as linear regression analysis and the analysis of variance are widely used in all areas of science. Thus there can be few numerate practitioners of the social and behavioral sciences who have not read research reports that employ these methods to fit linear or curvilinear relationships to data on the variables of interest.

The method of least squares was developed by Legendre, Gauss, and Laplace in the first quarter of the nineteenth century in the context of important practical problems in astronomy and geodesy. But it was not until later in the century that Quetelet (*see* Quetelet, Adolphe (1796–1874)), Galton (*see* Galton, Sir Francis (1822–1911)), Edgeworth (*see* Edgeworth, Francis Ysidro (1845–1926)), and Pearson (*see* Pearson, Karl (1857–1936)) among others adjusted this technique to the needs of the social and behavioral sciences. There was no great shortage of practitioners trained in the use of advanced statistical techniques, but such individuals as were active in this area were not able to treat their observations with the necessary level of detachment, so that the original source of the observations remained a significant feature of their subsequent analyses.

The method of least squares was absorbed relatively rapidly into psychology, but its rate of infusion into the economic, social, and behavioral sciences (other than psychology) was

more gradual. Indeed, applications of this technique were not at all common in these areas until well into the twentieth century. See Stigler (1986, 1999) for a detailed account of the gradual transformation of these subject areas (*see* Quetelet, Adolphe (1796–1874); Edgeworth, Francis Ysidro (1845–1926); Thorndike, Edward Lee (1874–1949)).

The history of the method of least squares clearly demonstrates that practical scientists with little or no interest in the social and behavioral sciences can make significant contributions to this subject area by developing general analytical procedures that can be adjusted to the particular needs of social and behavioral scientists.

Readers wishing to study Gauss's original work on the method of least squares will be reassured to learn that they do not have to read his texts in their original Latin as Bertrand (1855), Börsch and Simon (1887), and Trotter (1957) have translated Gauss's principal works on the method of least squares into French, German, and English, respectively.

Gay and Bisexual Latinos in US Gay Culture

Xavier L Guadalupe-Diaz, Framingham State University, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Gay culture and community in the US are rooted in shared histories of struggle, celebration, pride, and identity. As a diverse community, Latinos comprise a significant population among gay and bisexual men (GBM) in the US. The distinct lived experiences of Latino GBM often result in marginalization from both their broader communities and gay culture. While Latino cultures vary, overarching themes of machismo and familismo contextualize experiences of homophobia and heterosexism within their broader communities. In addition to gay identity development, racism and stereotyping, and impacts on health and well-being, various factors contribute to the relegation of Latino GBM in mainstream US gay culture.

The lesbian, gay, bisexual, and transgender (LGBT) community encompasses a diverse range of intersecting social identities along the lines of race, ethnicity, nation of origin, religions, gender identities, and more. Among these, Latino gay and bisexual men (GBM) characterize unique realities facing many other racial and ethnic minority groups within the broader context of mainstream American gay culture.

A brief note on nomenclature: The terms Hispanic and Latino are often used interchangeably. In the 2010 Census, Hispanic or Latino was defined as a "person of Cuban, Mexican, Puerto Rican, South or Central American, or other Spanish culture or origin regardless of race" (US Census Bureau, 2011). However, Hispanic generally refers to a group's relationship to Hispania, or modern-day Spain, while Latino more specifically refers to geographic origin; i.e., Latin America, Central America, or the Caribbean. Recently, the Pew Research Center's Hispanic Trends Project explored preference in terminology among 5103 Latino adults. Among the findings, researchers found that half of the sample had no preference in terminology. Nevertheless, for purposes of this article, the term Latino was chosen to describe those GBM with ethnic ties to any country in Central or South America or the Caribbean.

Within the broader scope of gay culture, Latino GBM face many of the same issues regarding stereotyping, cultural and religious problems, and racial disparities that other nonwhite GBM may experience. While Latin culture is vibrant and diverse with a variety of nation-specific qualities globally, overall there remains a strong, patriarchal emphasis that constructs rigid expectations for Latin men. Commonly referred to as 'machismo', the social constructs of Latin masculinity place heavy expectations on men to be emotionally distant, authoritarian, aggressive, and be a hypersexual heterosexual (Torres, 1998). Further, 'familismo' or familism places a heavy emphasis on the centrality of family. For Latino families, family interests take priority over individual pursuits or concerns (Ingoldsby, 1991). For Latino GBM, this means the pressures of heteronormative family structures and strong legacies of predominantly conservative Catholic upbringings may intensify feelings of shame.

Beyond these issues, in a predominantly white and middle-class-oriented gay culture, Latino GBM may often encounter discrimination or a lack of inclusivity in the gay community. While racism and stereotyping affect the broader Latino community, Latino GBM face specific adversities within the gay community. Some scholars have denoted this difference as general versus gay-related racism (Ibañez et al., 2009). Whereas general racism may refer to the larger attitudes and institutional biases on the basis of race, gay-related racism refers to racial biases within the gay community itself. These experiences may include rejection from potential sexual or romantic partners on the basis of race, being made to feel uncomfortable in gay settings, or sexual stereotyping and more.

Latin Cultural Issues and Gay Identity

Strong patriarchal and machista histories have unfolded and continue to dominate Latin communities around the world. Cultural dynamics plays a crucial role in shaping sexual identities, behaviors, and perceptions. While machismo informs Latin masculinity in a strictly heterosexual expectation, Latino GBM internalize the same narratives as heterosexual Latino men. While Latino masculinities are diverse, several aspects of machismo are central and frequently found across Latin communities. These narratives inform expectations about sexual identity and relationships that place men in dominant, active roles while women are passive or receptive partners. Scholars have argued that one such narrative of machismo is the representation of Latin masculinity as accomplished through penetrative sexual intercourse (Gupta, 2002; Reisen et al., 2010b). As women are expected to be the only receptive partner, homosexuality is assumed to involve being the receptive partner in male same-sex intercourse. Some scholars have argued that among Latinos, regardless of the gender of the receptive partner in penetrative sex, the insertive partner may still be perceived as heterosexual (Carillo, 2002; Finlinson et al., 2006).

In describing male same-sex penetrative sex, the broader American gay community popularly refers to the insertive role as 'top', the receptive role as 'bottom', and those who may perform either role as 'versatile'. In the broader gay community these roles are not rigid and most GBM describe taking versatile roles (Wegesin and Meyer-Bahlburg, 2000). For Latino GBM, tops are referred to as activos and bottoms are referred to as pasivos. As no universal term exists to describe versatile roles, some scholars have suggested that Latino GBM make stricter distinctions between activos and pasivos indicating a stronger adherence to a heternormative pattern in sexual dynamics (Carballo-Diéguez et al., 2004). Carballo-Diéguez et al., (2004: p. 160) argued that "activo and pasivo roles, especially in anal

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10261-2

sex, have radically different meanings for Latino GBM". As traditional notions of masculinity are linked to penetrative roles, pasivo roles are characterized as submissive and feminine. Machismo relegates pasivo roles to that of less than what an ideal man should be, privileging activo roles. This may contribute to the stigmatization of pasivo roles while excusing the homosexual behaviors of activo Latin GBM.

Familismo in Latin communities also commonly plays a crucial role in the development of gay identities. In comparison to Anglo family structures which may be more individualistic, Latino culture prioritizes the desires of the family unit over those of individual members. Traditionally conservative Latino family backgrounds contribute to the silencing of many Latino GBM especially when considering the high expectations placed on Latino men. As the family unit takes priority, the continuity of family lineages are rooted in a heterosexist expectation. Further, family rules pertaining to dating, abstinence, and marriage are highly regarded by Latino children. This may be more the case for Latino children born outside of the US as opposed to those who are American-born (Ingoldsby, 1991). For Latino GBM, coming out may seem like a selfish endeavor that would bring shame to the family and extreme disapproval. In addition, religiosity and adherence to traditional Catholic or other conservative Christian denominations characterize many Latino family backgrounds. Beyond the humiliation engendered on the family, Latino GBM also face rejection from religious institutions that have typically been central to the Latino family.

While much of what is known about these traditional cultural conflicts address a broader Latino culture, some differences may exist across nations of origin. Although some Latino nations such as Bolivia and Paraguay have constitutional bans on marriage equality indicating much stronger cultural resistance toward homosexuality, many other nations in Central and South America have legalized same-sex marriage or other unions. Argentina became the first nation in South America to legalize same-sex marriage in 2010 and more recently Uruguay has followed suit. Other South American nations including Colombia and Ecuador have legalized some form of recognizable same-sex unions. In addition, Mexico City and the Mexican state of Quintana Roo have both legalized same-sex marriage. These variations may suggest that differences across nations in Latin America exist along the lines of tolerance and the political acceptability of same-sex relationships.

Among Latino cultures, Mexican machismo is often thought of as more rigid and masculinist than others. Traditional Mexican gender norms illustrate similar patterns across other Latin cultures that may, however, have a stronger emphasis on bravado and independence. Some scholars have discussed similar narratives through the notion of the Mexican-vaquero or vaquero masculinity in Mexican culture (Gutmann, 2000). Vaquero, or cowboy, is an image of masculinity perpetuated through cultural narratives of manhood in Mexican culture and other Latin American countries (Taggart, 1997). In mainstream American culture, Mexican masculinity is often villainized as hypermasculine, aggressive, and sexist or demeaning toward women often in comparison to white masculinity. While these aspects of masculinity in Latino culture exist, overgeneralizations of Latino men lead to false characterizations. Utilizing a sample of 148 Latino men, Torres et al., (2002) challenged the 'myth of sameness among Latino men and their machismo'. The sample included Mexican Americans, Puerto Ricans, Central Americans, and Cubans among other ethnic identities. Using the Survey on the Application of Masculinity and Gender Role Identity Among Latino Men, the researchers examined machismo utilizing the Macho Scale, the Gender Role Conflict Scale, and the Mirandé Sex-Role Inventory. These measures assessed various aspects of machismo including sensitivity, dominance, emotionality, and more. Among the findings, only approximately 10% of the sample could be characterized by a machismo that was authoritarian, emotionally restrictive, and controlling. Additionally, Mexican Americans made the majority of a group classified as more flexible with gender roles and masculinity. These findings indicate that traditional aspects of machismo may not necessarily be uniform across Latino men and that wider range of gender ideologies is represented.

Stereotyping and Racism

Within the predominantly white, mainstream American gay community, Latino GBM face stereotyping and gay-related racism. Mainstream gay culture may often be characterized as highly commoditized and dominated by white, middle-class expectations of beauty and overall liveliness. In comparison to Asian and Pacific Islander and African American GBM, Latino GBM may not be so rigidly stereotyped sexually by mainstream gay sexual identities. While Asian and Pacific Islander GBM may be characterized as effeminate and submissive, African American GBM are often characterized as dominant and aggressive. These racialized sexual stereotypes in the mainstream gay community may be somewhat different for Latino GBM. Latino GBM may either be characterized as submissive or assumed bottoms or as aggressive, assumed the tops posture. As the Latino community ranges in skin color and body types, these aspects of racialized sexual stereotyping may vary. For example, even when considering all Latino GBM samples, Carballo-Diéguez et al., (2004) examined sexual role behaviors among 294 respondents and found that darker skinned and taller Latino GBM were expected to be activos or tops while those who were lighter skinned or shorter were assumed pasivos or bottoms. In the mainstream gay community, racialized Latino GBM hypersexual stereotypes may construct the aggressive narrative of a dominant Macho similar to those stereotypes faced by African American GBM. Conversely, racialized sexual stereotypes may characterize Latino GBM as submissive or exotic bottoms, similar to the narratives of submissive nonwhite masculinities among Asian and Pacific Islander GBM.

Beyond the general racism experienced by Latino GBM, mainstream gay cultural ideals and standards may also perpetuate racism in the community. Gay-related racism manifests in a wide range of ways including rejection by potential friends or sexual partners on the basis of race or a lack of inclusivity among gay scenes. Commoditized, white gay culture constructs expectations of attractiveness linked with lighter skinned and middle-class appearances (Diaz, 1998). For

Latino GBM, skin color and physical characteristics vary across ethnicities. These varying aspects of physical characteristics result in divergent experiences for Latino GBM. In one example, Ibañez et al., (2009) examined contexts of racism in a sample of 911 Latino gay men. The authors examined variations of experiences on the basis of skin color and physical characteristics (i.e., European, Indian, African/mixed race) among other factors. Further, measures of gay-related racism included aspects of sexual attention given, being treated unfairly, being made to feel uncomfortable at white gay clubs, and being turned down for sex or relationships, all on the basis of race. Among the results were high rates of gay-related racism experienced in the sample but also those factors of skin darkness and non-European physical characteristics significantly predicted greater experiences of gay-related racism. These findings echo others in the literature that illustrates the extent of racial biases in the gay community against Latino GBM (Ayala and Diaz, 2001; Williams et al., 1997).

Health

Cultural barriers, racism, and stereotype have resulted in several disparate outcomes in terms of the health and well-being of Latino GBM. Machismo and family expectations may leave many Latino GBM with little social support within their own communities. Coming out processes are further complicated when considering how central the family unit is among Latinos and the risk of losing vital connections to the community. Beyond the psychological impacts self-repression and/or family rejection, serious physical health consequences have been linked to the lack of discussion on homosexuality in Latino communities as well as to gay-related racism. In comparison to their white peers, Latino GBM are at higher risk for contracting HIV/AIDS (CDC, 2012). While accessibility to sexual health resources is more limited for Latino GBM, cultural factors also play a role in risky behaviors (Rhodes et al., 2011). Insertive role-donning Latino GBM may feel less inclined to use condoms and perceive that to be the responsibility of receptive partners. Further, machismo may involve taking riskier decisions which also influence the lack of safe sex practices (Reisen et al., 2010). Within the context of gay-related racism, Latino GBM may feel they have less negotiating power in sexual relationships. In particular, darker skinned Latino GBM may feel less inclined to request condom usage to attract more sexual partners (Ayala and Diaz, 2001; Ibañez et al., 2009). More recently, Mizuno et al., (2012) examined the influence of experiences with homophobia and racism in a sample of 1081 Latino men who have sex with men. Measures for experiences with homophobia included being beaten, treated rudely, or been made fun of; these experiences were inclusive to homophobia experienced within Latino groups and the broader community. In assessing experiences with racism, the researchers included aspects of gay-related racism. In addition to being beaten or treated rudely on the basis of race, the researchers asked whether they had "felt uncomfortable in a crowd of white gay men, had trouble finding a male lover or boyfriend or had been turned down for sex because of their race or ethnicity" (p. 726). Regarding gay-related racism, 29% of the sample reported having been uncomfortable in a crowd of gay men, 25% reported having had trouble finding a male lover or boyfriend because of race, and 26% had been turned down for sex because of their race; over 40% of the sample experienced both homophobia and racism. While experiences with racism were found to increase the likelihood of risky sexual behavior, those who had experiences with homophobia and racism were more likely than men who reported not experiencing so to report sexually risky behaviors such as unprotected receptive anal intercourse with a casual sex partner.

In addition to the impact that homophobia and gay-related racism may have on sexual options and risk taking, sexual health issues related to internalized homophobia have also been cited as particularly problematic among Latino GBM (Herrick et al., 2012). The internalization of homophobic attitudes and misconceptions about homosexuality has been linked to sexual risk taking and disproportionately affects Latino GBM (Diaz et al., 2001). As an impact on mental health and well-being, internalizing feelings of lower self-worth may result in greater apathy toward self-protection.

Latino Response

One way in which Latino GBM express community solidarity in an often hostile mainstream gay culture is by engaging in organizations, events, or activities aimed specifically at celebrating Latino LGBT and advancing Latino issues. In one example not limited to Latino GBM, 'United We Dream', an immigration social justice organization led by young activists, has expanded an ongoing initiative called the 'Queer Undocumented Immigrant Project' (QUIP). QUIP works to advocate and organize around issues facing undocumented Lesbian, Gay, Bisexual, Transgender, and Queer (LGBTQ) immigrants in the US. Often issues specific to the Latino LGBTQ community go largely ignored by larger, mainstream organizations working to advance gay rights. In 2013, during a large marriage equality rally organized by mainstream organization such as the Human Rights Campaign and the National Gay and Lesbian Task Force, organizers asked a QUIP speaker not to mention that he was undocumented (Brydum, 2013).

Washington DC, Portland, and Long Beach are among the American cities that host annual Latino-specific gay pride events. These events may highlight Latino-specific aspects of gay culture by featuring music, food, celebrities, businesses, and organizations that reflect the interests of the community. In cities or areas in which one Latino ethnicity is prominent, gay pride events are often hosted with specific emphasis to their culture. For example, Latino gay pride events in New York City may be more focused on Puerto Rican culture given the demographics of the city. Likewise, Latino gay pride parades in Los Angeles may reflect more Mexican and/or Central American themes. Several differences exist across Latino ethnicities which are often observable by diverse approaches to these pride events. In the Latino-American Caribbean, Cuba, Dominican Republic, and Puerto Rico communities, salsa, merengue, and bachata are popular music genres while Mexican or Central American genres may include more cumbia and ranchera genres. Various approaches to music influence diverse traditional dances, art and expression, and more. Beyond events, the

gay Latino magazine *Adelante*, is a national publication that highlights news stories, health topics, music, travel, and more. Coverage includes immigration reform and other political issues, arts, and literature by Latino GBM.

Overall, Latino GBM experience unique challenges both within their own cultural contexts and from the mainstream gay community. Recent estimates from the Pew Hispanic Center illustrate a changing dynamic in the Latino community regarding perspectives on homosexuality that indicate progress in acceptance. In the report, 59% of US Latinos responded that homosexuality should be accepted by society; for second generation US Latinos, this increased to 68% (Taylor et al., 2012). While these findings demonstrate a shift toward inclusion, addressing issues of sexual identity, health, and racial discrimination in culturally specific ways remain priorities in improving the lives of Latino GBM.

Abstract

Since World War II, the gay and lesbian movement in the United States has grown from a small network to a large movement. This article traces the origins of the US gay and lesbian movement from before World War II to the turn of the twenty-first century.

Introduction/Overview

The gay and lesbian movement in the United States developed in response to the growing public spaces for gay life, along with large-scale social changes initiated by World War II and urbanization processes. Although this movement has undergone many changes over time and includes many smaller movements, these movements have been fundamentally oriented toward outcomes of visibility and recognition, including recognition through the establishment of laws and policies. These movements have also become increasingly inclusive and expansive, including more attention to the role of class, race, and gender in gay and lesbian organizing, along with the inclusion of bisexual, transgender, queer, questioning, and intersex organizing at different points in time. This article divides the history of gay/lesbian movements into the closet era (pre–World War II), the beginning of the coming out era (World War II to Stonewall), gay liberation and lesbian feminism, human immunodeficiency virus infection/acquired immunodeficiency syndrome (HIV/AIDS), the Religious Right and culture wars, and same-sex marriage in the contemporary lesbian, gay, bisexual, and transgender (LGBT) movement.

The Closet Era (Pre–World War II)

The period before World War II is often referred to by sociologists as 'the closet era,' a time in which gay and lesbian identities were largely underground and unorganized. Although often referred to by scholars as 'the closet era,' historians suggest that 'the closet' was not a meaningful metaphor for gay and lesbian individuals during this time period (Chauncey, 1994).

The creation of a movement around gay and lesbian identities necessitates the development of the modern concept of the 'homosexual' as a certain kind of subject who is attracted to same-sex individuals. It was not until the mid-nineteenth century that the budding discipline of sexology and work by European sexologists like Richard von Krafft-Ebing, Havelock Ellis, and Magnus Hirschfeld developed a concept of the 'sexual invert,' an individual who defied gender norms with their behavior and attraction to individuals of the same sex.

However, the modern concept of homosexuality as a type of same-sex desire without being simultaneously marked by gender deviance was not developed until after the turn of the century. According to research by George Chauncey (1994) on the development of the gay world in pre–World War II New York City, in working class communities this modern concept of homosexuality did not develop until the 1930s.

According to scholars like John D'Emilio (1983), the development of industrialization and spread of wage labor created the conditions for the emergence of gay and lesbian culture. Capitalistic industrialization dramatically transformed family life, sexual relations, and heterosexuality, which in turn laid the conditions for public spaces such as gay bars. These developments also created different structural conditions for gay and lesbian lives, as white, middle-class men had more access to wage labor and urban public spaces. Before World War II, there was some early political organizing in the United States and abroad. This organizing included the German organization the Scientific-Humanitarian Committee created by Magnus Hirschfeld in 1897 and advocacy by gay men in New York City over police repression in the 1930s (Chauncey, 1994).

The Beginning of the Coming Out Era (World War II to Stonewall)

World War II dramatically transformed social life in the United States. It moved both men and women into the cities and into the military, creating more opportunities for homosocial connections independent of the family. In his groundbreaking book, *Coming Out Under Fire: The History of Gay Men and Women in World War Two*, Allan Bérubé (1990) analyzes the way military life during the war both constrained and created opportunities for gay men and lesbians to meet others and explore their sexuality. The war years facilitated entry into the gay world for many men and women at this time.

An urban gay subculture grew in the wake of World War II, in spite of growing public hostility toward homosexuality and the reinforcement of traditional gender roles in the 1950s. Exclusive gay bars were established in cities across the country (D'Emilio, 1983). The gay and lesbian bar was critical in creating the conditions for movement organizing due to the ways it created public spaces, solidarity, and collective identities (Kennedy and Davis, 1993). Although racial and ethnic minorities were frequently excluded from gay bars, black and

Hispanic gay men and lesbians may have congregated at house parties and urban drag balls often.

This growing lesbian and gay subculture was supported by Alfred Kinsey's work in the 1940s and his publication of the *Sexual Behavior in the Human Male*, which documented widespread experience with same-sex behavior among men. Kinsey's work disputed prevailing ideas that all adults were either homosexual or heterosexual and demonstrated instead that many adult men were sexually fluid (D'Emilio, 1983). By documenting the breadth of sexual variation, Kinsey's work aided gays in their efforts to describe themselves as something more than a very small minority with highly unusual behaviors.

This developing subculture provided a fertile ground for the first gay and lesbian activist organizations in the United States; homophile organizations devoted to educating homosexual men and women and engaging in small-scale social actions. In 1951, gay men founded the Mattachine Society in Los Angeles. The secret cell-like structure of the homophile organization was modeled after Communist organizations and allowed branches of the organization to be founded across the country yet operate in secrecy even from each other (D'Emilio, 1983). The lesbian homophile organization Daughter of Bilitis (DOB) was founded in the mid-1950s by Del Martin and Phyllis Lyon in San Francisco, and by the end of the 1950s, there were several DOB chapters across the country (Faderman, 1991). Both Mattachine and DOB published their own magazines (*ONE* magazine and *The Ladder*, respectively), and engaged in small-scale social actions, including protesting police entrapment in Los Angeles in 1952. During the more liberal 1960s, homophile organizations became more visible and confrontational. The visibility and growth of other movements such as the civil rights movement and student movement also buoyed homophile activism and enforced the viability of different tactics. For example, after the Homophile League of New York picketed a military induction center in the early 1960s, other homophile groups engaged in picketing in front of the White House and Pentagon (Faderman, 1991).

This increasing visibility included the involvement of gay men and lesbians in other social movements. For example, Bayard Rustin, a gay African-American man, was the lead organizer of the 1963 March on Washington for Jobs and Freedom. Lesbians were involved in the growing second-wave feminist movement, which gave them frames to interpret their relationship to gay homophile activists. The shift of lesbian organizing to feminist organizations led to the dissolution of the DOB in 1970 due to conflicts over feminist radicalism (D'Emilio, 1983).

The increasing militantism included riots and visible protest in US cities in the late 1960s, including rejecting police harassment at the New Year's Ball Raid in 1965 in San Francisco, at the Compton's Cafeteria in August 1966 in San Francisco, and at the Black Cat bar in Los Angeles in 1967 (Armstrong and Crage, 2006). The 'turning point' of this militantism is often described as the riot in response to the raid on the Stonewall Inn in Greenwich Village in the early hours of 29 June 1969. Gay bar patrons fought back against the police raid in an event that was commemorated and memorialized as the beginning of the contemporary gay and lesbian movement in the United States.

Gay Liberation and Lesbian Feminism

Although the growth of the gay liberation movement is often attributed to the riot at the Stonewall Inn, the strength of the movement probably resulted from the dramatic rise in radicalism in the late 1960s. Several movements including the civil rights movement and antiwar movement radicalized; this radicalism included growing discontent at institutions, expression of revolutionary sentiment, and cultural radicalism. Cultural radicalism included not only separatism but also the growth of the counterculture, which endorsed alternative gender and sexual norms for men and women.

The gay liberation movement developed quickly after Stonewall. The first gay pride march commemorated the riots in June 1970 and included thousands of men and women marching from Greenwich Village to Central Park (D'Emilio, 1983). Groups such as the Gay Liberation Front and Street Transvestite Activist Revolutionaries were established in New York City and San Francisco, but gay liberation organizations quickly spread across the country. This 'liberation moment' in the gay/lesbian movement included a new emphasis on 'coming out' to the public and on gay cultural pride, which was part of the influence of identity politics movements on gay liberation (Armstrong, 2002). Early gay liberationists were involved in other movements' actions along with taking to the street in more visible and radical forms of activism around issues like the criminalization and medicalization of homosexuality. This militantism was buoyed by the assassination of Harvey Milk, the first openly gay person to be elected to public office in California.

The politics of gay liberation in the United States was quickly beset by ideological differences, including a divide between revolutionary ideologies, redistributive political ideologies, and single-interest politics (Armstrong, 2002). These ideological differences materialized in group conflicts over whether or not to support Black Panther activities, which led to permanent splits and the founding of the more moderate single-issue group the Gay Activists Alliance. The movement also faced ongoing disputes about the inclusion of transsexuals and drag queens, along with the capacity of the groups to address sexism and racism. By the early 1970s, the modern gay movement struggled to include diversity within the community; although the ideological emphasis of the movement was 'unity through diversity,' this diversity was often limited to sexual and ideological differences between white gay men (Armstrong, 2002).

During this time, many lesbians became involved in lesbian feminism rather than gay liberation. Lesbians formed lesbian feminist organizations, including the Radicalesbians in New York, the Furies Collective in Washington, DC, and the Gay Women's Liberation in San Francisco (D'Emilio, 1983). In the essays 'The Woman-Identified Woman,' the New York Radicalesbians attested that "A lesbian is the rage of all women condensed to the point of explosion." Many lesbians focused on building separate women-only communities rather than engaging with male-dominated gay liberation, although by the end of the 1970s some lesbians had pushed for more inclusion in the gay liberation movement, which was increasingly referred to as the 'gay and lesbian movement' (Armstrong, 2002). Toward the end of the 1970s, there was also a sudden

growth in gay and lesbian organizations for racial minorities, particularly women's organizations (Armstrong, 2002).

Accomplishments of this burgeoning movement included the removal of homosexuality as a mental illness from the Diagnostic and Statistical Manual of Mental Disorders in 1973 by the American Psychiatric Association and inclusion of gay rights in the 1980 Democratic Party platform. Several national gay and lesbian organizations were also formed. Gay lawyer Bill Thom founded Lambda Legal Defense and Education Fund in 1972 and had to sue for the right of the organization to exist when New York courts denied the need for a legal voluntary organization for homosexuals (Anderson, 2005). Former GAA activists founded the National Gay Task Force in 1973. The Gay Rights National Lobby was created in 1978 and turned into the Human Rights Campaign Fund (now HRC or the Human Rights Campaign) in 1980.

In 1972, lesbian and gay college students in East Lansing, Michigan, helped pass the first local nondiscrimination ordinance that included sexual orientation. For the 14 local gay rights ordinances passed in cities and municipalities across the country between 1972 and 1974, there was little organized opposition, beyond routine objections from conservative community members or the Catholic Church (Button et al., 1997). These separate activities were organized into a national movement after the 1979 National March on Washington for Gay and Lesbian Rights (Ghaziani, 2008).

Although there were successes in the 1970s, there was also the beginning of an antigay backlash. When Dade County Commissioners passed a local nondiscrimination law that included protections for discrimination based on 'sexual preference,' it was the beginning of the first antigay backlash and national conversation about gay rights. The convergence of antigay, prolife, and antifeminist organizing led to the entry of evangelicals into the public life, creating a fierce countermovement in the form of the Religious Right that would fight with the gay and lesbian movement for several decades. In the mid-1970s, organized antigay activism grew out of small, localized social networks that ran through Christian churches and radio and television shows. Anita Bryant was a former Miss America contestant and spokesperson for Florida orange juice. She mobilized her followers in opposition to the newly passed nondiscrimination ordinance in Dade County, Florida, and her role in the opposition received national visibility. Bryant's campaign persuaded voters with language about religious rights and influence on children, implying that all gay men were pedophiles and looking to recruit children. The Dade County referendum in 1977 was the beginning of the first wave of antigay activism, a series of referendum campaigns that spread to cities across the country (Fetner, 2008; Stone, 2012).

HIV/AIDS

The growing momentum of the gay and lesbian movement was dramatically transformed by the discovery of the first diagnosed cases of HIV/AIDS in gay men in New York, Los Angeles, and San Francisco in 1981. Lacking a treatment for AIDS in those initial years, AIDS transformed the gay and lesbian movement organizationally and demographically. Movement resources, personnel, and leadership shifted into health-based organizations, which were often more bureaucratic and connected to the state than previous gay and lesbian activism had been (Armstrong, 2002). These organizations included early HIV/AIDS organizations, such as the Gay Men's Health Crisis in New York City. Some organizations and events were created to memorialize the growing number of people who had died from AIDS. Starting in 1985, longtime gay activist Cleve Jones also organized the NAMES Project AIDS Memorial Quilt, a patchwork of quilt squares in memorialization of over 90 000 people who died of complications due to AIDS. Events like candlelight vigils and Walk for Life memorialized and raised money for HIV/AIDS.

Growing anger toward the inaction of the Reagan administration on AIDS and the Supreme Court decision supporting sodomy laws (*Bowers v. Hardwick*, 1986) also led to a surge in gay militancy and the development of direct action politics, including the rise of AIDS Coalition to Unleash Power (ACT UP) in March 1987 (Gould, 2009). ACT UP targeted the funding of AIDS medical research, availability of drugs for treatment, and media depictions of AIDS.

According to some scholars, an additional consequence of HIV/AIDS was the growing focus on same-sex relationships and relationship recognition rights. The lack of relationship recognition for gay couples navigating the medical system due to HIV/AIDS and the growing lesbian baby boom in the 1990s led to greater attention to relationship recognition within the gay and lesbian movement and eventually the focus on same-sex marriage (Chauncey, 2004).

The Religious Right and Culture War 1990s

The gay 1990s included increasing visibility in the mass media, including the coming out of Ellen DeGeneres on her television show *Ellen* in 1997 and increasing inclusion of gay and lesbian television characters. Political recognition also grew, with the passage of new progay laws in state legislatures and Bill Clinton, the first presidential candidate to court the gay and lesbian vote (Ghaziani, 2008).

However, this visibility was coupled with a backlash against gay and lesbian rights. The 1992 Republican Convention sparked a culture war when the Republican profamily platform included a multipronged attack on LGBT rights in legislation, public education, and the arts. This backlash against the gay and lesbian movement played out in state legislatures and ballot boxes, with an increase in both progay and antigay state laws and ballot measures (Ghaziani, 2008). This convention was followed quickly by two of the most draconian antigay initiatives in Oregon and Colorado. In Oregon, the Oregon Citizens Alliance led by vocal antigay activist Lon Mabon sponsored a statewide initiative in November 1992, Ballot Measure 9. This was a broad, moralistic initiative that eliminated future and existing gay rights legislation, paralleled homosexuality with sadomasochism and pedophilia, and prohibited government promotion of homosexuality. In the same election, Colorado for Family Values sponsored Amendment 2, a broad legalistic initiative that eliminated future and existing gay rights laws in the state. They also developed a 'special rights' language that pitted African-Americans against gay rights and appealed to moderate voters. This

intensity continued until 1996. Between 1992 and 1996, antigay activists attempted antigay initiatives in 13 states and more than 30 cities and towns (Stone, 2012). In conjunction with this legal backlash, the exgay movement grew in the 1990s and became more public with its assertions that gay and lesbian individuals could be transformed into heterosexuals.

Some of this backlash was a result of LGBT legal gains. After the 1993 Hawaii Supreme Court case *Baehr v. Lewin* opened the door for same-sex marriage in Hawaii, legislators passed a federal Defense of Marriage Act (DOMA) in 1996 and a series of statewide statutory laws that reinforced DOMA. DOMA created a federal definition of marriage as between a man and woman, along with permitting states to ignore same-sex marriage performed in other states. In a few states, legislators referred these DOMAs to the ballot box to be overwhelmingly passed by voters and written into the state constitution (Stone, 2012). The 1993 "Don't Ask, Don't Tell" policy about gay and lesbian inclusion in the military was also a response to pressure from President Bill Clinton to allow gay and lesbian service people to openly serve in the military. However, some legal gains by the gay and lesbian movement were a result of ending antigay laws; specifically, the 1996 Supreme Court case *Romer v. Evans* overturned Colorado Amendment 2 (Fetner, 2008).

The 1990s was also a time period of political change for the lesbian and gay movement. National organizations grew larger and more involved in local and statewide activism (Stone, 2012). The movement grew increasingly institutionalized and focused on mainstream politics. Activism also became more specialized, as more groups developed for racial minorities, bisexual, and transgender individuals within the movement. The growth of bisexual and transgender organizations throughout the 1980s and 1990s led to pressure by bisexual and transgender organizers to be included in the mission and organization of the gay and lesbian movement, along with being included in the 1993 March on Washington (Ghaziani, 2008). The gay and lesbian movement turned into the LGBT movement during the 1990s, although bisexual and transgender individuals and issues continued to be marginalized within the movement.

The close of the 1990s saw two dramatic events: the legalization of same-sex civil unions in Vermont in 1999 and the murder of Matthew Shepard, a young gay man in Laramie, Wyoming.

Same-Sex Marriage and the Contemporary LGBT Movement

Although same-sex marriage was not a central goal of the LGBT movement in the 1970s, at the turn of the century it quickly came to the center of the movement agenda both in the United States and in many other industrialized nations. The movement for same-sex marriage is part of an international movement. The first nation to legalize same-sex marriage was the Netherlands in 2000, followed by over a dozen countries in Western Europe, North America, and South America, along with the nation of South Africa. By the start of 2013, in the United States, nine states and the District of Columbia had legalized same-sex marriage, and four additional states recognized same-sex marriages performed in other states.

Although contested by some activists within the LGBT movement, the push for same-sex marriage has been at the center of the LGBT movement agenda since the turn of the century. Some of this momentum has been motivated by organizers like Evan Wolfson, who was involved in Hawaii *Baehr v. Lewin* and went on to found The Freedom to Marry Coalition in 2003 to advocate for same-sex marriage. The 2003 Massachusetts Supreme Judicial Court ruling in *Goodridge v. Department of Public Health* that established the right of same-sex couples in Massachusetts to marry was the beginning of a backlash against same-sex marriage that diverted significant LGBT movement resources to the legalization of same-sex marriage.

Most of this movement energy was spent fighting antigay ballot measures that would ban same-sex marriage. Same-sex marriage has been voted on by the American public in a series of ballots measures across the country since 1998. Thirty of these ballot measures were legislative-referred initiatives to revise the state constitution to ban same-sex marriages. These marriage bans have passed overwhelmingly at the ballot box; they have been defeated only twice in Arizona (2006) and Minnesota (2012) (Stone, 2012). The most contentious ballot measure to date has been California Proposition 8, the only marriage ban to overturn legalized marriage. Proposition 8 countered a 2008 decision by the California Supreme Court to allow same-sex marriage. Between the California Supreme Court case and the campaign, more than 18 000 same-sex marriages were conducted in the state of California. The LGBT campaign to fight Proposition 8 and the Religious Right campaign raised over $40 million dollars, shattering campaign spending records. When Proposition 8 passed in the November 2012 election, there were protests across the country, and the marriage ban was contested in the Supreme Court case *Hollingsworth v. Perry*. Although these ballot measures have been a successful strategy for the Religious Right, the LGBT movement experienced its first winning streak in the November 2012 election, when voters in Minnesota rejected a marriage ban and voters in Maryland and Washington affirmed same-sex marriage laws that had been recently passed by their legislatures. Maine voters also passed same-sex marriage through an initiative that was proposed by LGBT organizers.

Marriage was not the only goal. There were many other LGBT movement accomplishments during this time period. For example, the overturn of sodomy laws in the Supreme Court case *Lawrence v. Texas* (2003) struck down existing sodomy laws in 14 US states. In October 2009, President Barack Obama signed the Matthew Shepard and James Byrd, Jr. Hate Crimes Prevention Act, which covered hate crime acts for both sexual orientation and gender identity. Later, President Obama repealed the ban on gay and lesbian service members, although transgender service members are still banned from the US military.

There were unsuccessful attempts to pass a federal Employment Non-Discrimination Act, which has been ongoing since the 1970s. However, there was a dramatic growth in nondiscrimination laws at the local level. As of 2007, over half of the US population was covered by a state, county, and/or city law against discrimination based on sexual orientation, whereas in 1990, less than a third of the population was covered by such laws. An increasing number of state and city laws also included

gender identity and expression, which offers more protection for transgender individuals (Stone, 2012). The passage of these local laws was a consequence of growing support in public opinion for LGBT rights, strength in local movement organizations, and assistance by national organizations.

The LGBT movement also increasingly focused attention on intersectional issues, such as immigration reform and social security. Transgender organizing and media visibility grew, along with the first national transgender rights organization, the National Center for Transgender Equality, which was established in 2003.

Future of LGBT Movement

Since the earliest homophile organizing at the end of World War II, the US LGBT movement has grown into a major social movement that has transformed homosexuality from a marginalized mental illness to a recognized minority group. The centrality of same-sex marriage to the LGBT movement has not only given the movement focus but also may diminish the significance of the movement after the legalization of same-sex marriage. It may be more difficult to sustain momentum in the LGBT movement once the goal of same-sex marriage has been reached. The centrality of same-sex marriage to the movement also has led to criticisms from scholars and activists alike that the LGBT movement has become more homonormative or focused on the integration of heteronormative ideals such as binary gender roles, marriage, and procreation into LGBT culture. This homonormativity may be contrary to the growing emphasis on diversity and inclusiveness in the LGBT movement, thus creating more divisions within the movement.

Abstract

This article examines gay and lesbian tourism and its relationship with gay and lesbian cultures and identities. First, an explanation is provided for why travel for some people became an integral part of their sexuality from the Victorian era through to the present day. Second, a critical overview is given of the role of the gay and lesbian tourism industry in producing and reproducing gay and lesbian identities with a special focus on events and festivals. Finally, the concept of risk (cultural risk and medical risk) is explored within the context of gay and lesbian travel and tourism.

Introduction

The gay and lesbian tourism industry sells travel products, such as tours, cruises, accommodation, or packages to attend events and festivals, specifically for same-sex attracted people. The niche lesbian, gay, bisexual, and transgender (LGBT) market is frequently positioned by industry commentators in economic terms as 'fast growing' and 'resilient.' Out Now Consulting, based in the Netherlands, estimated the income generated by the global gay and lesbian tourism industry at around US $165 billion per year (cited in UNWTO, 2012), while the United Nations World Tourism Organization (2012) estimated that the United States' gay and lesbian tourism market is alone worth US$65 billion. Community Marketing Incorporated (2009) noted the resilience of the gay and lesbian tourism market in the United States by highlighting that the number of holidays taken by American gay and lesbians remained unaffected by the global financial crisis in 2008.

Despite the financial strength of the gay and lesbian tourism market, a focus on market indicators alone masks a more nuanced understanding of this form of tourism. The starting point of market-led interpretations of the notion 'gay and lesbian tourism' is the assumption of stable, recognizable, and preconfigured 'gay' and 'lesbian' identities that comprise a homogenous market sector. Instead, our starting point is that participation in tourism contributes to the production and reproduction of gay and lesbian identities. In doing so, the social practices of purchasing and consuming products and services that comprise the gay and lesbian tourism industry is inevitably exclusionary as well as inclusionary (Waitt and Markwell, 2006; Casey, 2009; Binnie and Klesse, 2011). Statements about gay and lesbian tourism as a homogenous market category are therefore quite misleading. Indeed, many same-sex-attracted tourists may not identify particularly comfortably with a 'gay' or 'lesbian' identity for a range of reasons relating to ethnicity, culture, sociodemographic status, or religious affiliation.

To critically explore the gay and lesbian tourism industry, this article is divided into four sections. The first section charts the emergence of Western gay and lesbian tourism. This section points to how people with same-sex desires, and who had the financial and social capital, and the leisure time, traveled to destinations that offered some form of homosocial or homoerotic 'utopia,' long before the emergence of a fledgling, market-led gay and lesbian tourism industry in the late 1970s/early 1980s. The second investigates the relationship between tourism, consumption, and sexuality. Particular attention is drawn to how market relations inherent in gay and lesbian tourism enable particular understandings of sexuality to be produced and reproduced. The third section investigates the roles of festivals and events within gay and lesbian tourism. Here, attention is drawn to recent efforts by some festival organizers to unsettle the narrow definitions of 'gay' from market-led definitions or presentations of sexuality. The final section examines the notions of 'cultural' and 'medical' risk.

Emergence of Gay and Lesbian Tourism

In the nineteenth century, travel was integral to how affluent Western same-sex-attracted men and women explored their sexuality, often in spite of, rather than because of, an organized and integrated tourism industry. Why overseas travel became aligned with sexuality at this time can be understood in terms of how middle-class ideas of gender, race, religion, respectability, and morality became tied to reproductive sex and the nuclear family. The figure of the homosexual emerged in British Victorian society as a counter to the respectable, upstanding, Christian, heterosexual subject (Pronger, 1990). If the heterosexual subject was the keystone to a respectable, productive society underpinned by the nuclear family, the homosexual emerged as an 'illness,' an 'evil,' and a 'threat' to society. Laws were enacted to criminalize sodomy. Travel elsewhere for many same-sex-attracted men and women can thus be understood as a need to escape, albeit temporarily, from the heterosexist pressures and assumptions operating in Victorian society such as marriage and nuclear family life.

Due to there being more documented examples of the travel patterns of men in the nineteenth century, this section will focus on the growth of homosexual/gay male travel. Popular destinations at this time for same-sex-attracted, affluent British men included southern Italy (including Capri, Taormina, Palermo, and Naples), Spain, and northern Africa. In North America, affluent men in particular traveled to destinations such as Mexico, Haiti, and Cuba. Driving this 'north' to 'south' travel were ideas about the relationship between geography

and sexuality circulated by a form of neo-Darwinism and in the works of artists, writers, photographers, and other culture workers (Aldrich, 1993). Neo-Darwinist accounts of humanity described the people living in the tropics (and, for that matter, in Eastern Europe, Asia, and Africa) as sexually adventurous, promiscuous, with heightened libidos, and morally inferior to those living in Western Europe and North America (Waitt and Markwell, 2006). Such beliefs created and sustained a considerable level of demand among affluent Western men, regardless of their sexuality, to travel 'south' to seemingly less 'civilized' places and societies, where sex acts were not bound by European moral codes. Layered over this nineteenth century classed and racialized geography of 'sexual paradise' was the work of artists and writers that included August von Platen, Hans Christian Anderson, Andre Gide, and Wilhelm von Gloeden (Aldrich, 1993; Waitt and Markwell, 2006). These cultural workers were central to circulating ideas that configured places as 'homosexual paradises.' Imagined as utopias, these destinations were positioned as offering 'freedoms' from persecution and interference for men seeking sexual and social intimacy with other men. These quests had considerable resonance for affluent men whose daily lives involved considerable self-discipline to conceal their same-sex desires in order to avoid punishment by the law at the hands of their fellow citizens. For men whose lives were characterized by alienation, estrangement, or fear of being 'caught out,' these temporary sojourns may have been experienced in terms of personal freedom, and importantly, opportunities to become themselves. Helping creates the reputations of some destinations as a kind of utopia for same-sex-attracted men was the combination of less state surveillance in those locations, or a willingness to 'turn a blind eye,' and a marked disparity of wealth between the visitors and those visited, which may have facilitated sexual contact.

While, no doubt, there would have been knowledge passed by word of mouth about places safest to stay and socialize, these men did not have the benefit of a gay tourism industry to help facilitate their travel. Neither were there recognizable gay hotels nor were there gay bars or cafes. Men socialized at the homes of expatriates, inviting residents to join them, or frequented bars, restaurants, and cafes that were perhaps known to be tolerant of men who enjoyed the company of other men. More often than not, these men were alert to the possibility of being exposed, and subsequently disciplined their behavior and appearance to conform to and reproduce particular expectations of masculinity. These men visited and enjoyed these destinations facilitated through an informal network of relationships, information transmission, and situated knowledge provided by expatriates, rather than the bourgeoning tourism industry of the Victorian era. This was to emerge much later.

Following the First World War, greater acceptance of sexual diversity began to show in Western Europe, especially in the cities of Paris and Berlin, and, somewhat later, Amsterdam. While most European nations had laws that criminalized homosexual activity, specifically sodomy, in the nineteenth and the first half of the twentieth centuries, homosexuality began to be discussed, at least within intellectual discourses, in a more socially accepting way. The writings of Sigmund Freud and Magnus Hirschfield contributed to a more enlightened view of human sexuality, which embraced sexual difference such as homosexuality. During the 1920s and 1930s, Berlin became an important destination for homosexual men, and, as Vyras (1997: p. 24) has noted, "Berlin had become the destination, a kind of pilgrimage for homosexuals all over Europe." The British author, Christopher Ishwerwood, provides insights to how he negotiated his sexuality through the commercial venues that emerged in Berlin during the 1930s (see, for example, Isherwood, 1945). Homosexual 'subcultures' were able to flourish in Berlin and Paris through a combination of community-based political and social organizations together with commercial venues such as cafes and restaurants. Sibalis (1999: p. 25) commented that in Paris by the early 1900s, "a growing commercial world that catered to homosexual men comprising bathhouses, bars and restaurants had emerged." This mix of community-based structures and commercial venues had also begun to emerge in a number of North American centers as well, notably San Francisco and New York. Throughout the latter part of the nineteenth century and into the twentieth century, San Francisco, and particularly the Barbary Coast neighborhood, had a reputation for licentious entertainment and a growing tourist trade (Boyd, 2011; Waitt and Markwell, 2006). While European cities like Berlin and Paris became an integral travel destination for men seeking sexual relationship with men, in the early twentieth century, the imagined geography of the 'south' retained its pull. The Indonesian island of Bali, in the early twentieth century, became known as a 'homosexual paradise' (Vickers, 1989: p. 106), while central and South America, particularly the islands of Cuba and Haiti, and countries such as Brazil, attracted waves of homosexual men, who searched for, and found, sexual opportunities and freedoms that were largely unattainable in their homelands (Bleys, 1996).

From the 1960s to the 1970s, travel guidebooks such as *Damron's Men's Travel Guide* (first published as *Bob Damron's Address Book* in 1964) and *Spartacus International Gay Guide* (first published in 1971) targeted same-sex-attracted men. The publications chart the emergence of a commercial gay tourism industry because these guidebooks listed not only destinations but also the various components that comprise the gay tourism industry such as gay-operated or 'gay-friendly' hotels and resorts, cafes, restaurants, night clubs, discos, sex on premises venues, as well as 'gay beaches' and cruising areas. With the assistance of these guidebooks, men could now plan their holidays to destinations with the assistance of the hospitality infrastructure provided by the emerging gay tourism industry. These guidebooks are evidence of a shift from an unstructured and rather amorphous assemblage of operators and destinations to an integrated and commercial gay tourism industry (Waitt and Markwell, 2006). Magazines targeted at the gay male market such as *The Advocate* in the United States and *Gay Times* in the United Kingdom also began featuring travel sections and regular travel columns from the late 1960s onward.

By the early 1980s, the gay tourism industry started to become organized both internationally and nationally. In 1983, the International Gay and Lesbian Travel Association (IGLTA) was established (initially as the International Gay Travel Association) and today it is an association with more than 2000 member businesses from over 80 countries. There

are also nationally based gay and lesbian tourism organizations in countries such as Australia and Canada and regional organizations such as the Gay European Tourism Association. These organizations occupy an important position within the gay and lesbian tourism sector, acting as a vehicle to promote the interests of their members, lobbying government relating to policy matters, and raising the visibility of the gay and lesbian sector within the broader tourism industry. With the advent of the World Wide Web, a huge amount of gay and lesbian tourism and travel content can be found online. Indeed, a simple Google search using the term 'gay tourism' revealed 59 million results (compared with 'wildlife tourism,' 36 million; 'religious tourism,' 36 million; and 'cultural tourism,' 111 million).

Many businesses today describe themselves as 'gay friendly.' Indeed, many cities and towns also promote themselves using the same descriptor. Hodes et al. (2007) provide one of the few studies that have sought to understand tourists' conceptions of 'gay friendly,' in the context of Amsterdam. This work suggests that 'gay friendly' was not strongly attributed to material infrastructure such as the presence of hotels, bars, and nightclubs, but instead, their results indicated that 'gay friendly' is an amalgam of mostly intangible or embodied aspects of a destination, such as a feeling of being welcomed and accepted.

Nevertheless, as Boyd (2008: p. 226) suggests, the term has a rather 'amorphous quality.' At one level it seems apparent that 'gay friendly' means exhibiting genuine friendliness, acceptance, and hospitality to gay (and lesbian) people by an establishment that is owned and largely operated by 'nongay' people. This definition positions a 'gay-friendly' business as one that is not necessarily owned and operated directly by gay or lesbian people but rather by individuals or a company aiming to create a welcoming business where people do not have to feel afraid to disclose their sexuality. But to what depths does this friendliness extend? Is gay friendliness conditional on a reasonably narrow definition of 'gay'? Does gay friendly imply complete lack of discrimination or prejudice based on sexual identity? Within the context of gay and lesbian tourism, gay friendly suggests a welcoming approach to gay and lesbian tourists who are treated with the same dignity and respect afforded to heterosexual people. However, if a hotel proclaimed itself to be 'African-American friendly' or 'Chinese friendly,' it would surely be the subject of scorn, for a hotel would be expected to treat all cultures and ethnicities with equal respect. The notion of 'gay friendliness' then only really makes sense within a heteronormative framework, which positions nonheterosexual identities as 'other.' And how is a business' 'gay friendliness' to be measured or assessed? Should staff be trained in understanding the needs of gay and lesbian travelers, for example, before a hotel can call itself 'gay friendly'? Should there be some kind of accrediting process, similar to that which exists within the ecotourism sector, so that consumers can be reassured that a business has met certain standards of 'gay friendliness'? Gay friendly, as part of the smorgasbord of the tourism industry's marketing tools, is perhaps best understood as part of a neoliberal economic logic, where it is acceptable to be gay or lesbian so long as one remains within the boundaries of acceptable behavior and presentation of self that are proscribed by the heterosexual majority.

Tourism and Identity

Three strands of thought have emerged on the relationship between tourism and sexual identity. One strand of literature addressed this question by focusing on how travel for pleasure helps to make and remake a particular version of a 'gay' and 'lesbian' identity. Hughes (1997) positions recreational travel as a basic component of becoming gay and lesbian. Indeed, Hughes (2006: p. 83) suggests that "holidays have come to be one of the defining characteristics of what it means to be gay or lesbian." Most gay men do not have the responsibility of children (notwithstanding the increasing number of gay and lesbian couples who are indeed having children and also the relatively larger proportion of lesbians who have children as part of previous heterosexual relationships) and many (but certainly not all) gay men and lesbians have sufficient disposable income to allow them to enjoy more frequent recreational travel. It may well be that greater mobility is a characteristic of gay and lesbian cultures but this mobility depends on having sufficient disposable income and time. Rather than searching for difference, gay and lesbian tourists might, in part at least, be looking for sameness. Traveling to destinations with overt gay and lesbian precincts marked out with rainbow flags, retail outlets selling gay merchandise, and cultural expressions such as festivals and special events provide possibilities to validate a particular understanding of a gay and lesbian identity (Waitt and Markwell, 2006). Travel and tourism often facilitate the production and reproduction of a gay or lesbian identity that is constructed out of the interplay of the gay tourism economy with shared understandings of what it is to be gay or lesbian from ideas surrounding Western gay liberation history and politics.

A second strand of literature is critical of how the tourism industry narrows understandings of sexuality around particular versions of being 'gay' or 'lesbian.' The commodification of gay and lesbian identity through consumption practices tends to produce an exemplary gay and lesbian consumer who comes to be seen as representative of gay and lesbian identities. The emergence of a 'globalized gay consumer' (Waitt and Markwell, 2006: p. 248) excludes those who do not fit this subject identity because of such things as socioeconomic circumstances, ethnicity, or body shape. The images most frequently portrayed in gay tourism marketing collateral are normally male, young, white, and conventionally good looking. As Casey (2009: p. 159) notes, "The aged, disabled, fat or poor gay man has no place in travel imagery, advertisements or the destinations to be visited." Burns (2012: p. 316) makes the point that gay and lesbian tourism thus becomes a means for sustaining a 'global sexual citizenship' through a series of consumptive practices that privilege a very narrow conception of the gay or lesbian citizen – one that is "almost always a white western citizen-subject who has access to 'difference' through urban living, global travel and through his or her investment in the project of global queer world-making." Binnie and Klesse (2011: p. 159) advance this argument by noting that "while the right to consume and have one's identity recognized within tourist and city marketing can be seen as a marker of inclusion, this inclusion is often tied to a narrow construction of gay identity that is bought at the cost of exclusion of those who dis-identify with the commercial scene." Further, 'gay' or 'lesbian' identities

have emerged from within Western society, and although these identities have diffused to other non-Western nations, the degree to which they 'fit' with local understandings of sexuality and sexual identity is problematic, and can create difficulties for people trying to accommodate a (Western) gay or lesbian identity within their own cultures.

A third strand of literature has positioned the purchasing power of gay and lesbian tourists as leverage to achieve sexual equality. The intertwining of gay civil rights and the market is made very clear in the World Trade Organization's report on LGBT tourism, which states that "With a view to global tourism, many countries are beginning to realise that human rights considerations have also a positive effect on their economies and to actively promote LGBT tourism as a consequence" (Careaga and Sabbadini, 2012: p. 13). Because of the perceived economic impact of gay and lesbian tourism, organizations such as the IGLTA can use the purchasing power of its members (and by extension, the greater gay and lesbian market) to impact on government policies. Boycotts can be organized, either through industry organizations or by individuals using social media, through which gay and lesbian consumers can express their anger at governments or businesses that are perceived to discriminate against gay and lesbian customers. For instance, in 2004, activists in the Australian state of Tasmania urged gays and lesbians and their supporters to boycott Tasmanian gourmet food products because of that state's then antigay laws. However, gay activists today are urging Australian consumers to buy these very same products because of the current Tasmanian government's positive stance on gay marriage (Tasmanian Gay and Lesbian Legal Rights Group, 2012). Unfortunately, what is often overlooked in these arguments is the important question of whose sexual politics are advanced by the consumption practices of the gay and lesbian tourism industry.

Special Events and Festivals

Gay and lesbian tourism is powerfully driven by special events and festivals. Such events range in scale from international events hosted in 'world cities,' such as the International Gay Games and the World Pride event through to annual pride parades and festivals in regional centers – like Hamilton Pride, Waikato, New Zealand. Such events bring LGBT people together to collectively and publicly celebrate gay and lesbian cultures, reaffirm identity, and create enjoyment and, often, and importantly, public spectacle. It is the 'conspicuous spectacle' dimension of so many contemporary gay and lesbian events and festivals that differentiate them from earlier events that were often hidden and only known to 'those in the know.' Today, gay and lesbian communities create and host a diverse array of special events and festivals, which not only provide platforms for the production and reproduction of diverse sexualities but also frequently challenge heteronormative assumptions and expectations, and, at the same time, also attract a large nongay audience.

Perhaps, the most popularly known of all gay and lesbian events are the various pride parades and associated festivals. These events "challenge the production of everyday spaces as heterosexual" (Valentine, 1996: p. 152) through their use of public spaces (streets and roads) as a platform upon which to make visible gay, lesbian, and other nonheterosexual subjectivities. To give an indication of the scale of some of these events, it is worth noting that the 2011 Sao Paolo pride parade in Brazil was estimated to have attracted an astonishing "four million participants which included 650 000 tourists of which 15 000 were international tourists" (De Britto Lomanto, 2012: p. 19).

Many, if not most, of these events have become incorporated, to a greater or lesser extent, into the gay and lesbian tourism industry and indeed may serve as a gay and lesbian 'anchor attraction' for particular destinations. For example, the Sydney Gay and Lesbian Mardi Gras (SGLMG) has played a crucial role in helping to develop an identity for Sydney, Australia, as a welcoming and sophisticated gay and lesbian tourist destination (Markwell, 2002). Yet, its origins had little if anything to do with tourism, but instead was part of an ongoing political response to systemic discrimination that was being directed toward the lesbian, gay, bisexual, and transgendered citizens of New South Wales and indeed, Australia as a whole. Increased media coverage and a desire by LGBT citizens from other cities to participate in the parade or to witness the parade first hand led to the parade's growing intersection with the tourism economy. The parade, and the 2- to 3-week festival that developed, which is held prior to the parade, has become an important, and indeed, defining component of the gay and lesbian tourism industry operating not only within Sydney but also nationally. It was the international success of the SGLMG, which no doubt played a pivotal role in Sydney being awarded the International Gay Games that took place in 2002, 2 years after the Olympic Games were held in that city.

Gay and lesbian events and festivals are often critiqued as becoming somewhat "sanitized representations of queer identities and ways of living" (Binnie and Skeggs, 2006). This critique is mounted particularly for state- and corporate-sponsored events and festivals; the heterosexual 'mainstream.' This analysis of pride parades specifically, and gay and lesbian tourism more generally, posits festivals and events as sites of exclusion rather than inclusion. Furthermore, this line of argument suggests that pride parade organizers who collude with the interests of capital help to create an exemplary gay and lesbian tourist/consumer who is more interested in conspicuous consumption than in civil rights and fighting injustice. However, the annual global gay and lesbian events calendar also comprises events that radically challenge heteronormative assumptions around the appearance and behavior of bodies in public spaces.

The 'Queerball Strikes Back'! event (which was a street party that took place in New York in June 2012) is one such example. Organizers explicitly set about to 'trouble' the concept of the ubiquitous pride parade. While the event was small in numbers, the organizers raised the two general critiques of pride parades. First, that pride parades misrepresent the diversity of sexualities by privileging a white, middle-class, male parade participant. Second, that pride parades have 'sold out' because as the organizers of this event proclaimed, "we CAN'T BUY LIBERATION through corporate-sponsored Pride" (Anon., 2012). Another example is the Folsom Street Fair, held in September in San Francisco each year. The Folsom Street Fair is the penultimate event in that city's Leather Pride Week. In terms of its contribution to the tourism economy, the event draws something in the order of 400 000 participants and is

considered to be the third largest street event in California (Folsom Street Events, 2012). Billed as the world's largest leather event, this fair spreads out over a number of streets in the South of Market district, centered on Folsom Street. The event's origins lie within the city's gay and lesbian Bondage, Discipline, Sadomasochism (BDSM)/leather community. Norms surrounding sexuality are subverted through sexual acts of sadomasochism and bondage occurring on public streets during daylight hours and because many participants are either naked or seminaked, dressed in leather fetish gear. Importantly, bodies do not have to conform to conventional notions of sexual attractiveness – young, waxed, gym toned, and slim. Folsom Street Fair therefore broadens, rather than narrows, understandings of sexuality.

In contrast to the sexual freedom of Folsom Street Fair, gay and lesbian weddings and honeymoons, alongside pride events, are becoming increasingly integrated into the tourism industry in nations/states that have legalized same-sex marriage. Some cities now market themselves as gay and lesbian marriage destinations. For example, the American city of Baltimore offered wedding and honeymoons soon after legislation was passed legalizing gay marriage in Maryland (Yancey, 2012). Like pride events, evaluations of gay and lesbian wedding tourism is open to critique. On the one hand, gay wedding tourism offers possibilities to generate economic revenue, as well as to reconfigure destinations along the lines of social equality and 'gay friendliness.' This point is not lost on those advocating for gay marriage. For example, in New Zealand, the increased revenue generated from the tourism benefits of legalizing gay marriage are integral to arguments of proponents of changing the marriage act in that nation. On the other hand, as Boyd (2008: p. 228) suggests, "the commodification of gay marriage via the marketplace produces a new kind of queer citizen, one that participates in civic life via the social rituals of marriage and the commercial rituals of conspicuous consumption." Gay wedding tourism is another example of how expression of gay and lesbian sexuality and place is entwined within heteronormative assumptions – in this instance, monogamous couples and romantic love.

Risk

Tourist studies have conceptualized risk drawing on different schools of thought. In this section, attention is drawn to the insights offered to gay and lesbian tourism by two forms of risk: 'cultural risk' and 'medical risk.' Cultural risk draws on arguments that tourists are mindful of the social norms surrounding sexuality, ethnicity, religion, food, nudity, and so on when making destination choices. However, what we know about the social norms of sexuality in some nations suggests that cultural risks may play a more important role when people do not conform to the norms of heterosexuality. In some instances, the norms of heterosexuality remain institutionalized in law. Homosexuality or homosexual acts may be legislated as illegal, or homosexual citizens or visitors are positioned without any state protection from acts of prejudice or discrimination. For example, a small number of nations such as Iran and Saudi Arabia punish sodomy by the death penalty, while others such as Uganda, Jamaica, Belize, and Kenya may impose long-term imprisonment. A 2001 study by Amnesty International found instances where gay men who reported crimes at certain destinations such as Jamaica, the Caribbean, and Malaysia were "met with indifference and at worse face(d) further victimisation" (Brunt and Brophy, 2006: p. 290). People may choose to avoid nations in travel itineraries where they understand the cultural risks arising from sexuality as too high. Waitt and Markwell (2006) discussed the cultural risks that men opened themselves up to and the resulting compromises to their safety when visiting destinations such as Egypt and the islands of the Caribbean, where prejudice and discrimination toward homosexual people is coded within the law and where violence toward homosexuals is seemingly tolerated or even sanctioned by the state.

The concept of cultural risk is important to better understand why people who do not conform to dominant understandings of sexuality often find themselves as the object of victimization when configured as 'gay tourists.' Tomen and Markwell (2009) explored the cultural risks of visibility in places branded as 'gay friendly.' In their study of safety and hostility at a number of Australian gay and lesbian public events in the early 2000s, Tomen and Markwell (2009: p. ix) found what they called an "undercurrent of hostility, abuse and unreported violent attacks at these events, particularly in the aftermath of the Sydney Gay and Lesbian Mardi Gras parade." About 40% of the sample had experienced some form of hostility at one of these events and many participants employed a range of individual and group strategies to avoid hostility. These strategies included being careful about when and where to show overt signs of affection to their partner or friends, remaining within their friendship group traveling, concealing their appearance, or 'acting straight' on the way to and from the event (Tomen and Markwell, 2009). Likewise, the work of Brunt and Brophy (2006) found that victimization based on sexual identity was experienced either directly or indirectly by all the men in their sample of 20. The men in this study itemized physical assault, verbal abuse, threatening behavior, theft, and discrimination (Brunt and Brophy, 2006). Forms of discrimination were also considered by these men to be just as much a safety problem as victimization. The cultural risk identified in this study was the appearance of gay men who 'stood out from the crowd,' particularly those who did not conform to a conventional masculinity (Brunt and Brophy, 2006: p. 292). The authors concluded that the level of reporting of gay victimization and discrimination was underreported, suggesting a much greater level of incidence than official statistics might suggest. Discrimination, in all its various overt and covert, direct and indirect guises can sometimes be difficult to detect let alone measure.

The work of Hughes et al. (2010) illustrates that the cultural risks for gay and lesbian tourists may arise not from understandings of sexuality per se, but from notions of the respectful visitor. Hughes et al. (2010) in their study of resident attitudes toward men visiting a beach popular with gay men in Mexico found that residents rarely showed strong disapproval or dislike of homosexuality. Rather, residents expressed disapproval of overt sexual activity, and, to a lesser extent, nudism, in the 'public' spaces of the beach. However, the authors did suggest that there was "some indication of an underlying dislike of homosexuality, which was usually expressed in non-personal terms and probably a reflection of

deeper societal and cultural pressures" (Hughes et al., 2010: p. 783). The lack of respect shown by the number of visitors to the beach, rather than sexuality per se, was a source of contention. This points to how hostility toward increasing numbers of 'gay' visitors may be tied to understanding of respectable displays of affection and consideration for the integrity of the environment, which can frequently show evidence of damage from overuse or misuse at cruising areas.

Medical risks are the focus of health and behavioral scientists. Medical risks are defined by practices that increase the likelihood of long- or short-term harm by sustaining an injury or disease. For some people, becoming a tourist and engaging in relaxation is characterized by participation in a range of activities that involve practices associated with medical risks, such as excessive alcohol and recreational drug consumption, which might also lead to a greater risk of unsafe sexual activity. Indeed, some of the earliest research undertaken on gay tourism concerned aspects of sexual health, and, in particular, human immunodeficiency virus (HIV) (see Clift and Forrest, 1999, 2000; Luongo, 2000; Clift et al., 2002). Safer sex campaigns in affluent Western nations, built on scientific evidence of how HIV is transmitted, have been highly successful in reducing the infection rates of this virus. The fact that more people, including same-sex-attracted people, might be traveling to an ever-expanding range of destinations, does not necessarily mean this will lead to greater levels of HIV or other sexually transmitted infections (STIs). In other words, travel per se is not necessarily a risk factor in the acquisition of HIV or STIs. However, travel draws attention to the inequities in access to HIV therapies between the global south and north. Moreover, important questions are raised about how tourists from the affluent global north, who may be more knowledgeable about HIV, and its prevention, negotiate sex while traveling through the global south.

Results from a travel behavior study of British men who identified as gay suggested that 10% of the sample were "more likely to take sexual risks on holiday" (Clift et al., 2002: p. 187). However, the same study found that the proportion of these men who reported unprotected anal sex was around 15% (Clift et al., 2002: p. 188). The authors concluded that "while gay men are considerably more likely than heterosexual men to have sex with new partners on holiday, they are also are less likely to engage in unprotected penetrative sex" (Clift et al., 2002: p. 188). More recent research into gay men, sexual health, and travel (Benotsch et al., 2011: p. 402) found that a 'significant minority' of the men in their sample (which had been obtained from men attending a gay pride festival in Denver, Colorado) had engaged in medically risky sexual behavior, such as unprotected anal sex and substance use. Such results may point to the success of educational campaigns involving safer sex and condoms. However, as the authors noted, the participants in this study reported lower rates of both sexual and substance use behaviors associated with medical risk as well as 'lower motivations to seek sex' than reported in other studies (Benotsch et al., 2011: p. 403).

Conclusion

Travel is particularly important in fashioning Western gay and lesbian cultures. Traveling to other places, destinations at which sexual diversity is either imagined or legally recognized, continues to provide many people with possibilities to build and/or consolidate a gay or lesbian identity. The gay and lesbian tourism industry relies upon sustaining flows of visitors through marketing particular destinations (which may themselves wax and wane in popularity over time) as 'homelands' – Greenwich Village, New York, The Castro, San Francisco, Soho, London, and Darlinghurst, Sydney. As homelands, these locations offer opportunities to experience and learn about shared histories and cultures. Further, the gay and lesbian tourism industry relies on guidebooks, the World Wide Web, 'gay-friendly' businesses, and special events and festivals celebrating sexual diversity, to drive gay and lesbian tourism. However, gay and lesbian tourism is not without inherent contradictions and inequalities. The ways by which the gay and tourism industry is dovetailed with capitalist market forces through state and corporate sponsorship can lead it to be as exclusionary as it is inclusionary. Market-driven ideas of what it means to be gay or lesbian can create very narrow portrayals of gay and lesbian subjects. The profit-oriented imperatives of businesses mean that the gay and lesbian subject of the tourism industry is usually white, relatively affluent, middle class, conventionally attractive, and able-bodied – and also usually male. How sexuality intersects with the market forces too often compromises the social equality and social justice ambitions of gay and lesbian tourism. How sexuality intersects with travel, geography, and market forces of the tourism industry remains a crucial research agenda.

Gay Men's Emancipation Movement in Germany: 1897–1933

Jason Crouthamel, Grand Valley State University, Allendale, MI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

As has been true in contemporary actions for gay rights, tensions over gender identity in the early German homosexual rights movement presented a difficult challenge. This article provides an overview of the diverse scientific, ideological, and cultural perspectives on homosexuality within the male homosexual community in imperial and Weimar Germany. It also examines the effects of the World War I on how homosexual men conceptualized masculinity and the nature of homosexuality, and the struggle for civil rights in the Weimar years before the catastrophic Nazi seizure of power. Implications of German history for contemporary gay rights are noted.

This article focuses on the origins of the homosexual rights movement in Germany, its diverse ideological trajectories, the effects of the World War I on perceptions of homosexuals, and the struggle for civil rights in the Weimar years before the catastrophic Nazi seizure of power. Germany's founding homosexual rights movement engaged in debates that still persist in contemporary cultural wars: Is homosexuality natural? Are homosexual men essentially feminine or masculine? For scholars, it is important to consider that, similar to mainstream culture's debates over the heterosexual ideal, there was not a hegemonic image of the homosexual male within the newly defined gay community. The fragmented homosexual rights movement in traumatized and divided German history must be analyzed in its particular historical framework, but it also reveals the degree to which contemporary debates over gay identity and civil rights have precedents in over a century of struggle for homosexual emancipation.

In nineteenth-century Germany, an intersection of medical, political, and cultural developments led to the identification of homosexuality as an innate characteristic and a distinct identity. Based on this interpretation of homosexuality as a natural condition, German pioneers of the homosexual rights movement organized and mobilized against the criminalization of homosexual behavior. However, the homosexual emancipation movement was not a monolithic entity. The homosexual rights organizations that emerged in imperial Germany shared the goal of dismantling Paragraph 175, the section of the Prussian law code that criminalized 'sodomy' between men, but the movement was ideologically fractured over questions about the nature of male homosexuality. For scholars dealing with the history of homosexuality, this era presents substantial challenges. Sources produced by homosexual men who experienced discrimination and war in imperial and Weimar Germany highlight a fierce debate over the image of the homosexual male as a 'feminine' or 'masculine' being.

The Origins of the Homosexual Rights Movement in Late Nineteenth-Century Germany

Historian Robert Beachy demonstrates that the homosexual rights movement originated in Germany in the mid-nineteenth century, where the notion of homosexuality as a congenital trait was first defined by scientists and advocates for this sexual minority. Armed with the belief that homosexuality was a natural, inborn tendency, activists critiqued the criminalization of homosexuality as unjust (Beachy, 2012). In the wake of this new scientific theory, there emerged the first homosexual rights organization – the *Wissenschaftlich humanitäres Komitee* (WhK, or Scientific Humanitarian Committee), founded in 1897 by Dr Magnus Hirschfeld and his colleagues. Hirschfeld, a doctor, publisher, and supporter of the Social Democratic Party (SPD), saw the WhK as part of other movements for social reform and civil rights in imperial Germany, and one of the group's main goals was the dismantling of Paragraph 175 of the constitution, which criminalized same-sex behavior between men. The early homosexual rights movement was particularly focused on male homosexuality, in part because Paragraph 175 specifically targeted male homosexuality, and it reflected the broader cultural perception that female homosexuality was not a real phenomenon. The WhK worked vigorously to educate the public about the scientific nature of homosexuality and provided support to victims of Paragraph 175 and blackmail. Hirschfeld and his supporters collected petitions and lobbied Social Democrats sympathetic to reforming the law, and they published pamphlets and gave lectures on the biological nature of homosexuality (Steakley, 1992). Hirschfeld also reached out to broader sexual reform movements, including Helene Stöcker's League for the Protection of Motherhood and Sex Reform (*Bund für Muttereschutz und Sexualreform*), founded in 1905. Stöcker's socialist political leanings and organization of sex counseling clinics, also spearheaded by Hirschfeld's Institute for Sex Research, created natural groundwork for organizational and ideological alliances between the homosexual and women's movements in imperial Germany, between 1871 and 1914 (Grossmann, 1997).

Within the context of the late-nineteenth century medicalization of homosexuality, in which scientists began to define homosexuals in biological terms, Hirschfeld's WhK was an integral organization in the push to characterize male homosexuals as a separate, unique minority, a sexual intermediary, or 'third sex' with a partially female constitution that deserved both further scientific research and protection under the law (Oosterhuis and Kennedy, 1991). Homosexuality, he argued, could be recognized by its mental and physical symptoms,

including effeminate characteristics in manner, voice, and body. The WhK's interpretation of homosexuality and its cultural, political, and scientific significance was challenged by a homosexual men's organization founded in 1903, the *Gemeinschaft der Eigenen* (GdE, or 'Community of the Unique'), cofounded by Adolf Brand. An iconoclastic former teacher in Berlin who expressed both anarchistic and nationalistic rhetoric, Brand began publishing the journal *Der Eigene* ('The Unique One'), which was designed as a forum for male culture that celebrated *Freundesliebe* ('love of friends') as interpreted through a revival of ancient Greek celebrations of the male body and mind. Brand held up the Greek ideal of *Eros* as a goal that could liberate men from the shackles of bourgeois repression. He called for young men to discover the value of 'friend-love' in nationalist youth groups like the *Wandervogel* and the *völkisch* nudist groups who were part of a broader assault on prevailing bourgeois and sexual norms in imperial Germany (Ramsey, 2008). In their interpretations of homosexual identity, Brand's GdE and Hirschfeld's WhK were polar opposites. Brand and his colleagues sharply attacked what they saw as Hirschfeld's 'effeminate' classification of homosexuals. The idea that homosexuals possessed a feminine constitution was considered repulsive by members of the GdE, who envisioned an all-male utopia, or at least a society in which women were kept in their place as mothers and servants. Further, Brand argued, the biologists and sexologists had drained beauty from eroticism, and turned male sexuality into a base, scientific category (Oosterhuis and Kennedy, 1991), In contrast to Hirschfeld's WhK, the GdE had no interest in forming alliances with the women's movement. Similar to contemporary tensions in gay male culture and mainstream society identified by cultural theorist Judith Halberstam, Brand was antagonistic toward men who did not fit into a clear 'masculine'/'feminine' binary. Brand and his acolytes perceived 'alternative masculinities,' to use Halberstam's term, including women performing traditionally masculine roles, as a threat to male dominance (Halberstam, 1998).

According to historian Jeffrey Schneider, police surveillance of homosexuals in *fin-de-sieclé* Germany forced the community underground, but persecution was also a key catalyst in the formation of the homosexual rights movement (Schneider, 2012). Sources documenting Germany's homosexual community are rare, but there are sources that reveal the existence of a homosexual subculture, which imperial Germany's police was willing to tolerate as long as it remained contained and controlled. As Robert Beachy documents, the Department of Blackmailers and Homosexuals, created with the Berlin police force in 1885, demonstrated a 'tacit forebearance' of consensual homosexual sex. While the police placed surveillance on the gay and transvestite bars, keeping extensive mugshots of individuals described by police as 'pederasts,' reflecting widely held views that homosexual men preyed on underage males, homosexuals were allowed to form a community (Beachy, 2012). However, the German military was tainted by a series of public scandals over the discovery of homosexual aristocratic officers, most famously Count von Eulenburg in 1907, who were in the close circle of Kaiser Wilhelm II. These scandals shook the aristocratic officer corps and reflected anxiety about an epidemic of 'effeminate' and degenerate men in an institution that was supposed to be the epitome of masculinity (Funck, 2002). The Prussian War Ministry also recorded its anxiety about mostly working-class soldiers who cruised the streets, especially in Berlin, exchanging sex with mostly upper class civilians for money. The War Ministry portrayed these soldiers as innately heterosexual men who were being taken advantage of, reinforcing prevailing assumptions about soldiers as innocent victims morally corrupted by homosexual civilians. Similar to debates over "Don't Ask Don't Tell" in the United States in 1993–2011, many opponents to the integration of gays perceived them as sexual predators who threatened heterosexual soldiers. Within Germany's army barracks, soldiers who prostituted themselves were generally not stigmatized, or even considered homosexual, especially if they took the active, 'masculine' role in the sexual encounter with a passive, 'effeminate' partner. In imperial Berlin, the police tacitly accepted the homosexual subculture, and Paragraph 175, the 1871 law that prohibited 'unnatural fornication' (*widernatürliche Unzucht*) between men, was only lightly enforced (Schneider, 2012). The homosexual community would be seriously challenged, however, by the experience of the Great War (World War I).

The Effects of the World War I (1914–18) on Germany's Homosexual Rights Movement

The Great War profoundly traumatized millions of men, shattering their bodies and minds in industrialized violence. However, for many homosexual veterans, the war, despite its traumatic effects, opened up the possibility of social and political integration. At the same time, the homosexual rights movement remained ideologically divided, and it is important to examine the war's impact on the two main camps in the movement, Hirschfeld's WhK and Brand's GdE. Two of the original four members of the WhK were called into the army, and Hirschfeld mobilized scientists and activists in the WhK to study the broader sexual effects of the war (Steakley, 1992). The WhK also collected letters from thousands of soldiers on their war experiences and sexual behavior. Based on these data, Hirschfeld argued that the war created circumstances of physical and psychological deprivation that drove otherwise heterosexual men to seek sex with other men. Hirschfeld identified what he called 'pseudohomosexuality,' which he defined as heterosexual men engaging in homosexual behavior, which caused the most anxiety in military authorities who feared a breakdown of masculinity (Hirschfeld, 1930). Hirschfeld also found that the front experience enabled men who were 'constitutionally homosexual' to find other homosexual men in an environment that was more tolerant of same-sex relations than prewar or mainstream culture. The war did not create homosexual behavior, in other words, rather facilitated relations between homosexual men who were otherwise sexually and socially repressed before the war. Hirscheld identified three forms of 'intimate comradeship': the consciously erotic, unconsciously erotic, and bonds between men that remained unerotic. Hirschfeld recorded numerous accounts of men who discovered love with other men, and these relationships were often tolerated by their heterosexual comrades as natural examples of tenderness and love experienced between men in combat. While he was convinced that

homosexual men could easily adapt to their 'comradely' roles in war, Hirschfeld also pointed to numerous reports that exemplified his theory that constitutional homosexuals were essentially feminine, including accounts of soldiers who practiced transvesticism (Herrn, 2003). While he acknowledged that some men with homoerotic inclinations adapted easily to the militaristic culture of war, he argued that 'feminine homosexuals' ('feminine Urnings' or members of the third sex) were repulsed by the war and preferred the nurturing work of caring for the wounded and other 'feminine' tasks (Hirschfeld, 1930).

Adolf Brand and the GdE largely suspended its publications when many of its members, including Brand, entered military service. When Brand's publications resumed after the war and Brand himself returned after serving in the army, it was clear that the trench experience provided the GdE with new images and rhetoric for celebrating the ultramasculine homosexual male. In one of the first editions of *Der Eigene* published after the war, the GdE-sponsored journal adopted a militarized language where words like 'sacrifice,' 'the front,' 'battle' all began to permeate the movement's way of thinking about the relationship between homosexual men and the prevailing culture. Although Brand had long worshipped ancient Greek warrior ideals, the front experience of 1914–18 gave his organization a new context and language for articulating homosexual emancipation. The war, Brand insisted, proved that homosexual men were exceptional individuals upon whom the nation depended. He argued that they possessed the emotional characteristic – male love – essential for military life and thus the defense of the nation, and that this placed them in the elite of German society. One of Brand's acolytes, G.P. Pfeiffer, argued that 'physiological friendship' was the foundation for heroism, courage, and sacrifice displayed in war. War did not necessarily cause men to engage in homosexual behavior, Pfeiffer emphasized, but it did awaken intimate emotional bonds between men – comradeship – that transcended sexual instincts (Crouthamel, 2011).

The GdE's conviction that homosexual men were ideally suited to the defense of the nation resonated among other right-wing activists who saw the homosexual warrior as the core of a new society. Hans Blüher, a leading figure in Germany's *Wandervogel* movement since 1902, believed that the war demonstrated the essential role of male–male relationships in preserving Germany's future. Male–male relationships experienced in *Männerbünde* (male associations) were superior to heterosexual relationships, he argued, because women weakened men with their alleged spiritual and intellectual inferiority and pressure to conform to effeminate, bourgeois family norms (Bruns, 2008). Even some of the politically moderate homosexual activists made that case that homosexual men were particularly suited to enduring the strain of modern war because they were accustomed to emotional stress from persecution. In the 1919 issue of *Die Freundschaft* (*Friendship*), a newspaper that published articles by homosexual men from diverse ideological perspectives, one poem celebrated the bravery of homosexual men who must remain manly and unshakeable as they endure scorn. These themes were more explored in the novel *Alf*, written by Bruno Vogel in 1929. Vogel, a survivor of the trenches in Flanders and founder of the Leipzig branch of the WhK, compared the emotional stress of living under antisodomy laws to the traumatic experience of combat. In the novel, Alf consoles his friend Felix, who is arrested on the home front under 'their stupid paragraphs.' Writing from the trenches, Alf denounces the architects of the war and of Paragraph 175 as part of the same 'evil and stupidity,' and he promises to fight against both war and homophobia to help future generations. Alf portrays himself as emboldened by his combat experience to fight on behalf of the less confident and passive Felix (Vogel, 1929). Homosexual activists thus suggested that homosexual men, long experienced in the trauma of repressed emotions, were uniquely equipped to cope with the psychological trauma of war.

Military defeat in 1918 brought widespread accusations, especially from the political right, that 'enemies' at home had betrayed the army. Although some had argued that homosexuality fits very well with military victory, homosexuals, along with Jews, were frequently the targets of this 'stab-in-the-back' legend. In his pamphlet *The Sexual Cruelties of Love-Crazy Men*, conservative journalist H. A. Preiss lamented that the war led "normal men," as well as "intrinsically degenerate men," to turn to homosexuality, fetishism and other "abnormal sexual practices in order to relieve their tense nerves." Preiss claimed that veterans had become so focused on their abnormal sexual needs that they were no longer willing to sacrifice for the nation. Homosexual activists were self-conscious about how society perceived these new warriors for social justice, and they sought to combat 'stab-in-the-back' accusations. Instead, homosexual veterans characterized homosexuals as responsible members of the national community whose war experience entitled them to be accepted members of the community. In 'Against What Do We Fight?', veteran and contributor to *Die Freundschaft* B. Eden depicted homosexual men as warriors dedicated to protecting the nation and German values. Within this context of defeat and intensifying political fragmentation, homosexual activists struggled to make their case that the war experience made homosexuals comparable to heterosexual citizens, and thus deserving of respect (Crouthamel, 2011).

Divisions in the Movement during the Weimar Republic and the Crisis of Hitler's Rise to Power

Defeat and revolution in 1918 highlighted the disparities between Germany's homosexual rights organizations. When Germany lost World War I, revolution broke out, the monarchy was overthrown, and, after a brief civil war, a coalition of prodemocratic parties formed a constitutional democracy called the Weimar Republic in 1919. Germany's defeat traumatized Brand's hypernationalistic GdE, which perceived the new Weimar Republic as a threat to its elitist ideals. In Brand's universe, defeat and democracy threatened to annihilate the superior warrior-male. In contrast, the politically progressive WhK and the politically moderate *Bund für Menschenrecht* (BfM – League for Human Rights), cofounded in 1923 by businessman Friedrich Radszuweit, saw Weimar as an ideal opportunity. The broader movements for social revolution and sexual reform that intensified in the 1920s gave the more progressive and moderate homosexual rights organizations, which endorsed the ascendant prodemocratic parties, a new context in which they could argue for the decriminalization of

homosexuality, their long-held priority. However, it was not only Weimar's new social and political context that gave homosexuals confidence to articulate goals for legal reform. Politically moderate and progressive veterans from the WhK and BfM also employed the militarized language of the trenches, and the new image of a homosexual warrior-activist, to justify the abolition of Paragraph 175. In contrast to the WhK's medical and scientific focus on homosexuality, and the GdE's concentration on the aesthetics of 'friend-love' and the nationalistic identities of homosexual men, Radszuweit's BfM focused on the democratic and legal concerns of integrating homosexuals into the social fabric. The BfM concentrated on championing the individual rights of homosexual citizens, and they hoped to unify homosexuals across the political spectrum to support the legal demand for homosexual rights (Ramsey, 2008).

Homosexual veterans from both moderate and progressive perspectives idealized the front experience, and they saw themselves as the ultimate models of the struggle and exceptional victims of oppression who tragically suffered under both war and Paragraph 175. Their newspaper articles focused on militaristic values of fighting, sacrifice, and vigilance. This rhetoric was especially aggressive in *Die Freundschaft*, the most widely circulated homosexual periodical at that time. Homosexual veterans called upon their colleagues in the movement to avoid wallowing in the pain of war-time suffering and instead channel their energies into the postwar battle to bring homosexuality into the light and take pride in one's identity. The fight for homosexual emancipation, writers for *Die Freundschaft* argued, was an ideal path for simultaneously healing the wounds of war and securing a place and purpose in postwar society. In his 1919 article 'Dead Sunday' (*Totensonntag*), for instance, veteran A. Lange compared combat in the trenches and postwar combat to gain psychological and political freedom. Lange suggested that the same spirit of sacrifice found at the front lived on in those fighting for homosexual emancipation (Crouthamel, 2011). Lange's postwar experience reflected that of many gay veterans around the world who after World War II and subsequent wars gained confidence to come out of the closet and organize activism in the fight for civil rights (Vickers, 2009).

The postwar battle fought by homosexual men was not just for political emancipation; it was also a battle for the image and perceptions that homosexual men held of themselves. The new postwar political movements had little room for 'effeminate' men. For Adolf Brand and the GdE, this was not a change, as Brand celebrated comradeship at the front as an ideal hypermasculine environment, an all-male utopia where 'real men' could explore ideals of eros without the feminine restraints imposed by bourgeois culture. In a 1930 GdE-supported publication, *Eros*, a supplement to *Der Eigene*, Brand tore apart the conservatives' image of homosexual men as antithetical to the warrior ideal. Specifically, Brand attacked the Nazis' claim that "man-man love emasculates our *Volk* and makes one the play-thing of one's enemies." Brand lamented that homophobes who denounced homosexuals as weak and effeminate symbolized society's complete failure to understand homosexuality. Despite all the scientific work done on homosexuality by his rival Magnus Hirschfeld, Brand claimed that little progress had been made to educate the public on the reality of 'friendship' and homosexual identity (Crouthamel, 2011).

Progressive reformers also embraced a warrior image for the homosexual activist. *Die Freundschaft* welcomed contributions from homosexual activists who represented warrior masculinity in a positive light. One writer for *Die Freundschaft* portrayed homosexual men as battle-hardened veterans, and he specifically targeted men "who clean themselves like young girls and go play and dance" as useless in the new fight. Effeminate homosexuals were weakening the struggle: "We need men, complete men (*ganze Männer*). Effeminate men (*weibliche Männer*) are no good for battle and conflict"(Crouthamel, 2011).

Ironically for the left-wing WhK and moderate BfM, the most public controversy over whether or not homosexual men were really 'masculine' and capable of warrior virtues was fought over the openly homosexual Nazi Stormtrooper, Ernst Röhm. Social Democrats and other left-wing parties used Röhm's homosexuality as a lightning rod to denounce his moral character. While the WhK and BfM shared the SPD's ideological disdain for Röhm and the Nazis, they defended Röhm's personal character, arguing that he was a victim of prejudice and hypocrisy, and that his sexual orientation should be a private matter that had no bearing on his moral qualifications for leadership. The BfM's Friedrich Radszuweit saw Röhm's commitment as a political fighter as evidence that he was entitled to be treated as any other member of society, regardless of his sexual orientation. Radszuweit chastised the SPD's homophobic motives and alleged hypocrisy when *Vorwärts* published a cartoon depicting a Nazi leader standing behind a row of Stormtroopers, Hitler's elite street fighters, and the caption: "As your leader I'm right behind you." BfM activist Paul Weber reminded the SPD of its long-standing commitment to decriminalizing homosexuality, and noted that among its members and leaders were numerous patriotic, upstanding homosexuals (Herzer 1995). Radszuweit stressed that the party should be consistent in its commitment to treating homosexuality as a private issue and he called on the left to confine its critiques to the Nazi party's worldview and politics. Referring to the role played by men like Röhm in the war, Radszuweit emphasized that homosexuals "have performed great things for their *Volk* and for their countries." The presence of loyal party comrades in the Nazi movement, BfM activists carefully pointed out, should be a lesson to the Nazis that homosexuals are productive members of society: "One should take note that the National Socialists have learned something from this scandal: that homosexuals are also capable and decent people who can be useful, and that these men are entitled to the same rights to exist as every so-called normal citizen"(Crouthamel, 2011).

Despite Radszuweit's call for greater tolerance, the Nazis targeted homosexuals as enemies of the 'racial state' once they came to power in 1933. The Nazis perceived homosexual men as effeminate, degenerate 'asocials' who polluted the nation's racial health and tarnished the image of the hypermasculine warrior ideal (Mosse, 1998; Burleigh and Wippermann, 1991). When Hitler ordered Röhm executed in 1934 after the latter's expressed intent to take over the army, Röhm's homosexuality was used as a pretense. The head of the Schutzstaffel, Heinrich Himmler, began a campaign of violence against homosexual

men and promised to purge them from German society. The Nazis quickly modified the Paragraph 175 law, expanding it to criminalize any perceived homosexual intimacy, including gestures, in addition to the prohibition on sexual intercourse between men. Virtually overnight, the homosexual subculture and community that flourished in Weimar Germany was eradicated. Hirschfeld's Sexual Research Institute was destroyed, gay venues were shut down, and homosexuals were sent to concentration camps. There was wide consensus for Nazis' antihomosexual measures, as the regime's perceptions of homosexuals as 'asocials' were shared by many ordinary Germans (Pine, 2007).

Conclusion

In order to analyze the experiences and perspectives of homosexual men in early twentieth-century Germany, it is important for historians to recognize the homosexual community's diverse perspectives on the nature of homosexuality. While Hirschfeld and many of his adherents argued that homosexual men were an essentially feminine, 'third' sex that should be accepted, many homosexual men who experienced the comradeship and militarization of the Great War asserted that they were masculine warriors who fulfilled the hegemonic gender ideal expected from heterosexual men. This new image of the hypermasculine, homosexual warrior-male came to permeate the movement, which identified these ex-front fighters as ideally suited to carrying out the battle for civil rights and social integration. While the gay community in the 1920s found its path for arguing that homosexuals were made into 'real men' through the war experience, others still perceived them as enemies of the 'national community,' as evidenced by the violence orchestrated by the Nazi regime against gay men after 1933. Embracing the hegemonic image of masculinity did not substantially alter the gay community's status as 'social outsiders' in the eyes of mainstream culture. Even after the collapse of Nazism in 1945, Paragraph 175 remained law until 1969, when, after an international movement for homosexual rights intensified in the wake of the Stonewall riots in New York, homosexuality was finally decriminalized in Germany. For contemporary gay politics, the early twentieth-century homosexual rights movement in Germany reveals that, since its origins, the homosexual rights movement has constructed diverse interpretations of homosexual identity, and the movement's attempts to convince mainstream society that homosexuality is natural has been a difficult challenge. While decriminalization has been followed by greater integration of homosexuals into mainstream society, perceptions of homosexual men as deviant persist, despite attempts by homosexual men to assert that their identity is consistent with, or even essential to, the interests of the nation.

Gay, Lesbian, and Bisexual Youth

Ritch C Savin-Williams and Kenneth M Cohen, Cornell University, Ithaca, NY, USA

This article is a revision of the previous edition article by R.C. Savin-Williams, L.M. Diamond, volume 9, pp. 5892–5895, © 2001, Elsevier Ltd.

Abstract

Gay, lesbian, and bisexual youth have multiple developmental trajectories that consist of a number of milestones, the order and timing of which vary across individuals. After considering the deceptively simple constructs of who is gay and how many nonheterosexual youth exist, we review what is known about early feelings of being different from peers, the onset of same-sex attraction, sexual questioning, first sexual experience, recognition and self-labeling, disclosure to others, first romantic relationship, and self-acceptance.

Introduction

This article is based in part on Cohen and Savin-Williams, 2012. Same-sex attracted youth have always existed throughout history and across cultures. What is unique to contemporary society is that far more youth now label their sexuality as gay, lesbian, or bisexual. By constructing a sexual identity based on their sexual orientation, sexual behavior, romantic relationships, and, perhaps, a lifestyle, they are at the vanguard of making sexuality a critical component of personal identity. Although adolescents may experience their same-sex oriented self as newly emerged or energized with the onset of puberty, it nonetheless likely has been present from birth and will remain fundamentally unchanged on the deathbed.

During the past four decades, research on same-sex oriented youth has provided an increasingly sophisticated and nuanced understanding of their lives. Here, we focus on the development of the individual from first memories to self-acceptance. This process is an evolving and frequently lengthy one, consisting of multiple developmental milestones that vary in order, intensity, timing, and significance across individuals. This empirically validated perspective corrects previous conceptions of gay youth development as following universal, invariant, and steplike identity stages.

Evolution of Gay Youth

Although homoerotic youth have been described by artists, poets, religious writers, and historians for hundreds of years, it was not until the early 1970s and 1980s that medical, public health, and clinical professionals began investigating youth who they labeled as gay (and hence creating a new sexual category) as a unique group with its own exceptional developmental characteristics. This research cast doubt on earlier interpretations of adolescent same-sex sexual encounters as experimental, puberty-inspired outcomes unrelated to an inevitable heterosexuality.

Early research studies primarily comprised small samples of adolescents identified as gay whom investigators could identify and entice to participate – overwhelmingly youth in trouble and in need of social and mental health facilities (runaways, delinquents, prostitutes, suicide survivors). Some of these youth were being served by social service agencies such as New York City's Institute for the Protection of Lesbian and Gay Youth (later, the Hetrick-Martin Institute and its affiliated Harvey Milk School) that were established in large urban centers to address the physical, social, educational, and therapeutic needs of gay youth. Not surprisingly, the findings from these studies highlighted what was believed to be the ubiquitously difficult lives of gay adolescents who inevitably were in dire peril. As information accumulated, the portrait that emerged was both simplistic and monolithic. The representation of gay adolescents as necessarily suffering miserable and risk-filled lives, sometimes referred to as the suffering suicide script (Savin-Williams, 2005), was widely accepted as truth.

Few researchers at the time questioned whether these participants were representative of most youth with a same-sex sexuality. For example, the first empirical study included 60 young men, many of whom were urban hustlers living on the fringes of society (Roesler and Deisher, 1972). Predictably, many who visited gay bars recounted high numbers of sexual encounters (one reported over 3000 sex partners) and sought mental health counseling for depression and suicidality. Most felt rejected and disdained and few were hopeful about their destitute lives. A second study published over a decade later, again with a similarly exceptional youth population, explored the social stressors that placed gay (again, male) youth at high risk for physical and psychological distress (Remafedi, 1987). Many boys reported emotional difficulties, poor grades, school truancy, substance abuse, sexually transmitted infections, crimes, suicide attempts, and hospitalization for psychological reasons. Despite this morbid profile, Remafedi concluded that it was 'unlikely' that his adolescent sample was biased because the mere act of negotiating a gay or bisexual identity during adolescence placed one at risk for dysfunction.

The legacy of this early research has left an indelible impression on the minds of public policy makers, health care providers, educators, parents, and youth: being young and gay is intrinsically risky with little hope for a positive outcome. Although the research data were embraced to buttress arguments for the inclusion of gay youth in health care services and as a protected class, slow to emerge has been research that challenges this single trajectory characterization.

During the past two decades, scholars from other disciplines (particularly the biological sciences and developmental and

social psychology) have addressed normative gay development with representative samples of youth. As a result, an empirically based portrait has emerged, which is more nuanced and complex. It is these data that we present in this article.

Domains of Sexuality and Romance

Sexuality has various domains or expressions, including erotic attraction or fantasy (sexual orientation), behavior (genital contact), cognitive (sexual identity), and, perhaps, emotion (infatuation, romance). The first three are most frequently used by researchers when they define a sample as being of gay youth, but the four are imperfectly related to each other. For example, a young man might be sexually attracted to both sexes (bisexual sexual orientation), have sex only with females (heterosexual behavior), develop crushes on men (homosexual romance), and identify as heterosexual because he sees this pattern as the only option given by his family and religious community. A young woman with homoerotic desires (homosexual sexual orientation) might have sexual experiences with both sexes (bisexual behavior), romantic relationships with men (heterosexual romance), and a lesbian identity for ideological reasons. Depending on the domain assessed, radically different conclusions about a youth's sexuality can be reached.

Sexual orientation refers to the balance of erotic thoughts, attractions, feelings, and fantasies that one has for members of a particular sex or multiple sexes. Likely the consequence of genetic variation or the prenatal environment and its effects on brain development and sexual orientation are probably present from birth and as such is relatively immutable, stable, and resistant to conscious control. Most commonly, sexual orientation is assessed by asking participants about their sexual attractions or fantasies as represented by a scale ranging from exclusively male to exclusively female. Self-report measures, however, can be problematic because individuals are not always aware of their sexual orientation or are unwilling to disclose it.

One potential resolution is to use biometric measures that capture automatic or unconscious responses. These assessments can mediate the distortions of data from participants who are unaware of their sexuality or who are concerned about social stigma and hence report their sexuality in what they perceive to be a socially desirable manner. Psychophysiological measures of sexuality include genital arousal, functional magnetic resonance imaging (fMRI), electroencephalography, eye dilation, and eye tracking. The most common of these measures is genital arousal that assesses penile and vaginal response to sexual stimuli. More recently, fMRI brain imaging and eye tracking/dilation have been used to identify neural and attentional correlates of sexual arousal networks that differentially respond to preferred and nonpreferred sex stimuli. As opposed to traditional self-report measures of sexuality, the possible benefits of these two include the assessment of a wide range of participants across ages and cultures (e.g., non-English speaking).

Sexual behavior refers to the genital activities in which an individual engages. Definitions of what constitutes sex vary across individuals, cohorts, and societies and can refer to disparate activities such as vaginal or anal intercourse, oral/genital contact, and any manner of genital/genital contact between two or more people. The reference to sexual behavior includes proportion directed to each sex (i.e., ranging from exclusively females to exclusively males) and frequency of activity (e.g., 'daily,' 'within the past month,' 'once in the past year,' to 'never had'). A challenge to accurate measurement of sex is that cultural factors such as social class, geographic region, religious affiliation, and race/ethnicity influence the choice of sexual behaviors and partners and these might not be consistent with an underlying sexual orientation.

Sexual identity is a socially constructed label self-chosen to represent an array of potential sexual and romantic situations. Sexual identities are limited to those available within a given culture and historic time and as such the interpretation of particular labels, and even the specific identity terms used, varies. For some, a sexual identity is based on sexual feelings, attractions, behaviors, or some combination of these. Compounding these complex issues, some contemporary youth reject traditional sexual identity labels altogether, including the terms lesbian, gay, and bisexual, in favor of specific descriptions that better represent their sexuality and, frequently, gender expression (e.g., mostly straight, sexually fluid, pansexual, gender queer). Other youth reject sexual categories because they loathe being boxed in or simplistically designated by their sexuality.

Infatuation is an essential aspect of what might best be considered, *romantic orientation*. Infatuation or crush refers to an emotional, irrational state of being in which an individual feels blissfully passionate about another and subsequently believes she or he is 'in love' with the person. The feelings are generally considered to be short term, intense, and additive in quality as an individual becomes obsessed with increasing occurrences by the infatuation she or he feels. The object of desire can be unattainable (e.g., a rock star, a popular upperclassman, a straight friend), is unaware of the infatuation, or fails to reciprocate the feelings. The relationship between infatuation and romantic love is thought to be orthogonal or, perhaps, related to the extent that infatuation frequently precedes romantic love. The way in which a crush can grow into mature love and intimacy is unknown, especially among same-sex attracted youth. Although infatuation is believed to be derived from libidinal attraction, the relationship between sexual and romantic orientation is essentially an unchartered territory, in large part because the latter, especially as expressed in romantic behavior and romantic identity, has seldom been defined or assessed.

Recent research illustrates the intricacies of these various sexual and romantic indicators for the current generation of youth. For example, the majority of those who engages in same-sex behavior identifies as heterosexual and the majority of nonheterosexually identified individuals experience heterosexual behavior and romance. So, too, about 1 in 10 heterosexually identified youth report same-sex attraction or fantasy, and some youth fall in love with someone to whom they are not sexually attracted (as well as the reverse). Thus, it is most reasonable to conceptualize sexual orientation as existing along a continuum with exclusively heterosexual individuals and exclusively homosexual individuals at the poles and nonexclusive individuals – those who vary both in degree (e.g., 70% other-sex and 30% same-sex attracted) and domain (e.g., sexually attracted to girls and romantically attracted to boys) of their sexuality – somewhere in between.

These discrepancies have been attributed largely to the effects of external stigma and the resulting sexual prejudice that some

youth internalize. Although few aspects of the self are as essential as sexual and romantic longings, youth may struggle to self-recognize, disclose to others, and fully embrace their underlying same-sex sexuality. They may be unaware or distrusting of their sexual desires because they have limited exposure to nonheterosexual alternatives, conservative family attitudes, attenuated libido, or excessive self-monitoring of expressed behavior. As a result, they may vacillate between rejecting a socially stigmatized sexual identity and being true to self. These irregularities appear to be decreasing for the current cohort of youth, perhaps because their generation is far more comfortable with sexual and gender diversity during a time when society in general has dramatically shifted its views toward sexual prejudice and nonheterosexuality (Savin-Williams, 2005).

After considering the deceptively simple construct of how many gays exist, we review what is known about developmental milestones that together constitute the process of identifying oneself as a gay. These milestones include early feelings of being different from peers, the onset of same-sex attraction, sexual questioning, first sexual experience, recognition and self-labeling, disclosure to others, first romantic relationship, and self-acceptance.

How Many Gays?

Beyond verbal admission that one's sexual orientation is not heterosexual, the determination of sexual orientation is unexpectedly complex, depending on the way in which it is defined. Consistent with issues raised previously, it is necessary to distinguish among three related sexual domains: sexual orientation, sexual behavior, and sexual identity. Data from four waves (12 years) of the National Longitudinal Survey of Adolescent Health (Add Health) corroborate this point. Prevalence rates of nonheterosexual youth vary between 1 and 20%, and are highest among young women, those who identify as mostly heterosexual, and those who acknowledge same-sex attraction but do not necessarily identify as gay/lesbian (Savin-Williams et al., 2012). By the age of 28, 2 and 4% of Add Health men and women, respectively, identified their sexual orientation as gay, lesbian, or bisexual; however, more than 6% of men and nearly 20% of women claimed that they were not exclusively heterosexual (see table below). Thus, not all youth with same-sex sexuality necessarily identify as gay, act on their sexual desires, or disclose the nature of their sexuality to others, perhaps especially not to adults perceived by youth as having narrowly defined ideas about what constitutes sexual identity.

	Straight	*Mostly straight*	*Bisexual*	*Mostly gay/lesbian*	*Gay/lesbian*
Women	80%	16%	2%	1%	1%
Men	94%	4%	1%	1%	2%

One Trajectory or Many Trajectories?

Coming-out stage models, many of which were proposed during the first two decades of research on gay youth, characterize development as an invariant, universal progression from initial unawareness and confusion to eventual identity pride and synthesis (Cass, 1979; Troiden, 1979). Despite the widespread popularity of stage-based coming-out models, linear and idealized portrayals have not been empirically substantiated. For example, whereas identifying as gay usually precedes disclosure to others or same-sex dating, some youth have a committed same-sex romantic relationship prior to self-labeling. Youth may identify as gay and remain a virgin, although stage theories often posit engagement in sexual activities with others of their sex prior to self-identification. In contrast to previous generations, it is not unusual for contemporary youth to forego sexual confusion or to be without fear that they are mentally ill for being gay; almost from the start, they calmly believe that it is just who they are.

Because recent research has documented the variability of developmental milestones, most scientists are now wary of assumptions about what are normal or typical developmental trajectories. The coming-out process is best understood as an individual's achievement of developmental sexual and romantic milestones that increasingly occur without respect for tradition, timing, and order.

Feeling Different

The vast majority of same-sex attracted youth recalls growing up feeling different or manifesting behavior or interests discrepant from those of their peers. This sense of divergence from other children can begin as early as first memories and tends to intensify with age. The recalled aspect of differentness frequently involves gender expression – having the personality, interests, or behavior of the other sex. In one study, by the age of 8 years, two-thirds of youth who later identified as gay or lesbian were considered gender atypical by others and over half reported that their parents said that they were gender inappropriate; half of such parents attempted to change the youth's gender presentation (D'Augelli et al., 2008).

Feeling different because of perceived gender inadequacy often perseveres throughout adolescence and into adulthood and relates to deficiencies in gender conformity (e.g., low femininity in women), elevations in gender nonconformity (e.g., high masculinity in women), or both. In one study, men reported that their initial feelings of being different were determined less by inappropriate sexual longings than by the shame generated by their feelings of gender ineptitude (Troiden, 1979). By adolescence, however, another source of differentness emerges – feeling sexually different because of homoerotic desires, sexual interactions with the same sex, and negligible erotic attraction for the other sex.

Although the correlation between same-sex attraction (addressed below) and gender-atypical behavior is not perfect, many studies document a strong association (Cohen, 2002). Nonetheless, some heterosexual youth report gender-atypical interests (being a male dancer) and some homosexual youth report gender-typical pursuits (being a football quarterback). Many youth find it easier to suppress the behavioral expression of their homoeroticism (a lesbian eschewing sex with girls) than to conceal gender nonconformity (a lesbian walking in a masculine manner), possibly because the latter is less subject to conscious control.

Same-Sex Attraction

The age range during which youth first experience same-sex attraction is broad, extending from first memories onward, though it usually first occurs several years before the onset of puberty (during adrenarche, 7–9 years of age). Although supporting empirical evidence is limited, a decline in the recalled age of first attraction of about 4 years, particularly among girls, has been observed since the 1980s. Whereas previous cohorts of boys reported awareness of their sexual attraction earlier than girls, this is less true today, likely the result of young women's growing acceptance of all aspects of their sexuality (Diamond and Savin-Williams, 2009; Rosario et al., 1996).

Relative to boys, girls more frequently remember their first same-sex attraction as romantic rather than sexual. For example, in one study girls were more likely to recall their first same-sex attraction as an emotional attachment or crush; boys, as a sexual thought, arousal, or behavior (Savin-Williams and Diamond, 2000). Whether this reflects differences in biology, socialization, or both is unknown. However, it is frequently reported that female sexuality is more dependent on environmental, situational factors, such as passionate, interpersonal relationships with women and university courses with strong pro-feminist readings and lectures (Diamond, 2008; Peplau, 2003).

As a predictor of sexual identity, the presence of sexual attraction for one or the other sex might not be the best indicator. Many heterosexually identified individuals, especially women, report some degree of same-sex attraction, prompting several researchers to argue for a revised sexual identity taxonomy that would include the label *mostly straight* (Thompson and Morgan, 2008; Savin-Williams and Vrangalova, 2013). In addition, as many as 80% of lesbians and 60% of gay men experience opposite-sex attraction and fantasy (Rosario et al., 1996). Developmentally, sexual attractions consistent with one's sexual orientation emerge earlier than attractions that are not; regardless, the onset of sexual attraction awareness may be unrelated to the timing of other developmental milestones, such as coming out to self and others, dating, and accepting one's sexuality.

Overall, most youth report that they are not disturbed by their early homoeroticism because it feels natural, enjoyable, and a reflection of who they are (Savin-Williams, 2005). When these desires fail to dissipate with time, suspicion that one might not be heterosexual can prompt an interval of sexual questioning, uncertainty, or elaborate denial that may be fleeting or last a lifetime. Increasingly, however, contemporary gay/lesbian youth are less likely to question their sexuality because they know almost simultaneously that same-sex attraction signifies a sexual minority status. Sexual identity resolution may be more confusing and problematic for individuals who are attracted to both sexes or are primarily heterosexual yet experience same-sex attraction or engage in same-sex behavior.

Questioning Assumed Heterosexuality

When same-sex attraction becomes especially frequent or undeniably intense, youth who previously considered themselves heterosexual might wonder whether the attraction has meaning for their sexuality – that is, whether they might be less than totally heterosexual. Such questioning can intensify over the course of adolescence and lead to clarity or confusion, which in turn elicits divergent resolutions, not all of which include the assumption of a sexual minority identity label. Perhaps they believe it is a phase or experimentation, or that everyone has homoerotic feelings; these views allow individuals to minimize or discount their sexual desires. Others might consider their sexual fantasies – but not themselves – to be gay, or, if they are willing to assume more personal responsibility and acceptance, they may concede that they are slightly gay.

Having any degree of heterosexual interest and behavior might convince some youth that they are, or can be in the future, totally straight, as long as they try hard enough and maintain focus on the other sex. This belief allows them to preserve hope for an eventual heterosexuality even as they acknowledge and perhaps derive pleasure in their same-sex sexuality. Increasingly, youth who accept their same-sex attraction as memories previously considered innocuous come to assume greater meaning and support the naturalness and intractability of their homoeroticism. For youth with some heterosexual interest, the result might be a self-label as mostly straight, bisexual, or sexually fluid. In each of those three categories, more young women than men reside and, in most surveys, their prevalence exceeds those who identify as lesbian, usually by a factor of two or three (Savin-Williams et al., 2012).

Sexual Behavior

Although the average age of first same-sex encounter (specific types of sexual activity are seldom given) is around 14 years for both sexes, the onset of sexual activity can precede, co-occur, or follow self-recognition as a gay, lesbian, or bisexual person. That is, self-identified gay virgins do exist and sexual minority youth, similar to heterosexual youth, may delay sexual activity until they are in love or are in a committed relationship. Corresponding to the increasingly younger age of first awareness of a nonheterosexual identity, the majority of contemporary youth now embraces a same-sex identity prior to experiencing same-sex behavior (Savin-Williams, 2005).

Most same-sex oriented adolescents do not participate exclusively in same-sex behavior. Reasons are varied, including a desire to experiment or have fun, pressure while dating an opposite-sex peer, alcohol intoxication or substance use, and genuine heteroerotic desire. Although some straight-identified youth engage in same-sex encounters, those who are primarily homoerotic pursue such interactions with greater regularity and zeal and reportedly derive greater physical and emotional satisfaction from them (Vrangalova and Savin-Williams, 2010).

Same-sex oriented young men are more likely than same-sex oriented young women to report same-sex behavior, to have a greater number of sex partners, and to engage in such activities prior to heterosexual experiences. The first same-sex encounter among young women typically occurs with a friend or someone they are dating, but for young men it is more likely to take place in the context of a purely sexual encounter, despite stated preferences for relationship sex

(Savin-Williams, 2005). Although the documented sexual fluidity among same-sex oriented women may explain their greater participation in heterosexual encounters, they may also be exposed more frequently than young gay men to opposite-sex sexual invitations. Nonetheless, the majority of both sexes engages in heterosexual sexual activity, typically within a dating or friendship relationship (Diamond, 2008; Diamond and Savin-Williams, 2009).

Self-Identification

Coming out to oneself – that is, recognizing that one's same-sex attractions, crushes, fantasies, and behaviors are meaningful and signify a nonheterosexual sexuality – is a milestone that some youth vividly recall. This is especially true for those who experience the realization as either terrifying or relieving, and is less the case for youth who have always known what their homoeroticism means for their sexuality and personal identity. The latter trajectory is becoming increasingly common as contemporary cohorts are appreciating and naming their sexuality while still in middle school or high school or, in some instances, even while in elementary school (Savin-Williams, 2005).

Whereas young men may take months or even years to process the meaning of their same-sex attraction and progress from comprehension to self-identification as gay/bisexual, young women typically make the transition to lesbian/bisexual far more quickly. It is not uncommon for women to recognize, name, and disclose to others their homoeroticism within a few days or months, or even shortly after developing their first crush on another young woman (Savin-Williams and Diamond, 2000). Bisexuals may take longer to reach these developmental milestones because their sexual identity is somewhat more fluid over time, they have fewer sources of support, or they face disbelief from others about their sexuality (Rust, 2002).

Transcending traditional labels of same-sex sexuality, some youth are redefining sexual identity categories or rejecting them altogether. That is, a growing constituency of youth is refusing categorical sex-based labels, accepting notions of sexual and gender fluidity (e.g., pansexual, heteroflexible), and describing their sexuality as an interaction between their erotic preferences and their gender expression (e.g., transboi). Sexual self-definitions may be dynamic and unspecified (e.g., sexually fluid), a conduit for amalgamating multiple identities (e.g., black dyke who loves men), or a rejection of sexual taxonomy altogether (e.g., unlabeled, 'I love Robert').

Other youth eschew sexual labels because they fear negative family or social repercussions or they prefer to emphasize other aspects of their life that they consider to be more personally meaningful, such as their religion, race/ethnicity, or geographic region. Still other youth reject traditional sexual classifications because they associate particular stereotypes with those labels (lesbians as butch; gay men as sissies) that they find abhorrent. Consequently, youth might acknowledge their same-sex attraction and behavior but deny that they are gay, lesbian, or bisexual.

Diamond's (2008) prospective longitudinal investigation found that many same-sex attracted women considered their sexuality to be fluid and that most had experienced several changes in their sexual identity (but not sexual orientation) since childhood. Quite common was the belief that sexual labels are limiting and that individual characteristics trump gender in determining romantic interest. Although some young women with same-sex interest or activity eventually embraced a heterosexual label, they insisted that their same-sex attractions persisted.

Disclosure

Coming out to others can be a lifelong process during which same-sex attracted youth face decisions regarding whether, when, and how to reveal their sexuality to family, friends, coworkers, and new acquaintances. Disclosure to others can be a positive event that facilitates personal integrity, identity synthesis, and psychological health or a negative event that engenders ridicule and threats to physical safety. For young men, disclosure usually first occurs several years after coming out to self. As noted previously, the gap between the two for young women is somewhat less. The recipient of first disclosure for both young men and women is a best female friend, though it is no longer rare to first reveal one's sexuality to a favorite sibling, another same-sex attracted youth, or a supportive heterosexual male friend. When the object of first disclosure is carefully chosen, the reaction is almost always positive, even celebratory. Indeed, today's generation of MTV-viewing, Internet-consuming young adults routinely consider sexual diversity to be normal and positive and thus are typically nonplussed when peers come out (Savin-Williams, 2005). It is not uncommon for friends to progress quickly from mild surprise (or amused confirmation) to resolute determination that they will find a sexual or romantic partner for their friend.

Unique challenges, however, may confront youth who are foreign nationals temporarily residing in North America, members of conservative racial/ethnic or social class groups, or religious members of orthodox communities. For cultural reasons they may be unable or unwilling to live a same-sex active or oriented sexually open and integrated life, and thus their priority is to avoid real or feared widespread social admonishment. Although little is known about these mostly invisible youth, they likely face unique barriers in coming out to self and others as they attempt to reconcile their atypical, unacceptable sexuality through the lens of their primary family and social community (Greene, 1994). Beleaguered, they may be left alone to navigate their sexual development within the context of a mostly white gay subculture in which disclosure problems related to racism, classism, or religion are not acknowledged or challenged. For other youth, the considerable support they receive from their primary family or community outweighs the advantages of coming out, at least during adolescence and young adulthood.

Another subgroup of sexual minority youth who encounter particular hurdles disclosing to others are gender-nonconforming individuals whose cross-sex behavior and interests deviate significantly from those of their peers. They may be assumed to be gay because of their gender expression, perhaps long before they realize the connection themselves. The harassment they face from peers who are antagonistic

toward anyone who fails to act as a boy or girl 'should act' may delay their own self-awareness because such insight would acknowledge the truthfulness of the hated peer accusations.

Despite these barriers, disclosing one's sexuality to others can be an act of empowerment and self-affirmation, a means for obtaining personal authenticity, social support, and interpersonal closeness. It frees those with same-sex attraction from the trepidation and feared rejection they long anticipated. Reasons for not disclosing include fear of the unknown, avoidance of disappointing others (especially parents), and the belief that they will become irrevocably boxed in ('what if I later discover I am not gay?'). It is noteworthy that today's youth are increasingly worried about being chastised by friends who are insulted because they were not told earlier ('you did not trust me!').

Young people may delay disclosing to parents not because parents are deemed unimportant, but precisely because of their importance. Thus, youth want to be absolutely certain about their sexuality before they make this final, most highly significant, disclosure. Some delay coming out to parents because of the general discomfort youth of all sexual orientations experience when discussing sexual matters with parents; others, because they fear emotional devastation and financial ruin (e.g., lost academic financial support) should parents reject them. Surprisingly, even gay-affirming parents with gay friends and progressive politics may be among the last to know about their child's sexuality because their daughter or son wishes to avoid the anticipated parental enthusiasm and encouragement to bring home a romantic partner sooner than she or he would like.

Nevertheless, adolescents who come out to a parent (the mother is usually first) while living at home seldom face rejection or expulsion. Parents might not be initially thrilled with having a gay child because they fear for the child's safety, are concerned about what their neighbors or parents will think, or worry that their dreams of grandchildren are dashed. However, despite stereotypes and highly publicized instances of abuse and condemnation, youth seldom receive an ongoing, severely negative response. Parental reactions vary from celebration to rejection, but with time most eventually accept what they had long suspected (Savin-Williams, 2001). Similar to their children, parents have been helped by normalizing media portrayals and the coming out of friends and coworkers.

Romantic Relationships

A desire for a committed romantic relationship is articulated by many sexual minority youth. Until recently, such a relationship was considered unobtainable until high school graduation when living away from home would render them somewhat immune from the judgmental and punitive eyes of parents and hometown peers. Thus, the first same-sex date frequently occurred while a freshman in college or when entering the workforce. Although most youth continue to postpone dating until such times, the growing cultural acceptance of sexual diversity and expanding peer support (e.g., school-based Gay-Straight Alliance clubs) are increasingly motivating young people to come out while still in high school. Consequently, same-sex dating and taking a same-sex partner to the prom are no longer extremely rare occurrences.

This growing visibility of same-sex dating and romance was evident in a study documenting that sexual minority youth did not differ from heterosexuals in number of romantic relationships, especially for those who were most out and thus most able to identify and attract potential dating partners (Diamond and Lucas, 2004). Youth in romantic relationships were also less likely to be depressed or anxious (cause and effect were not addressed). Nonetheless, sexual minority youth were more likely than heterosexuals to fear not finding the type of relationship they wanted, and sexual minority young men, in particular, faced obstacles in developing highly intimate same-sex relationships during their teen years.

As with heterosexual dating, few of these early relationships endure, yet they afford important opportunities for psychosocial exploration, integration of emotional and sexual intimacy, and acquisition of a positive identity. Locations and strategies for finding partners mirror those of heterosexuals, although nonheterosexuals also face unique challenges. For example, sexual minority youth must search within a smaller pool of potential partners containing many who are closeted and perhaps unidentifiable. Consequently, they may convey interest toward individuals they erroneously believe to be romantically or sexually available, creating possibly awkward, if not dangerous, repercussions.

Self-Acceptance and Synthesis

Considered in many coming-out identity models to be among the final developmental stages, acceptance of one's sexuality and its synthesis with other aspects of personal identity can be achieved at any point in the life course. Those who attain sexual identity synthesis recognize the importance of their sexuality but no longer experience it as all-consuming or overarching; it is simply one of many aspects of self. Thus, a woman who earlier defined herself as a lesbian novelist would now see herself as a novelist who happens to be attracted to women.

Despite earlier stereotypical representations of the tragic lives of gay youth, contemporary sexual minority youth are as content with their lives as are heterosexuals (reviewed in Savin-Williams, 2005). For example, two-thirds of lesbian and gay adolescents reported feeling anywhere from indifferent to very good about their sexuality; less than one-tenth expressed a desire to not be gay. If given the option, most would not take a magic pill to make them straight. Some youth are content with their same-sex orientation without identifying as a sexual minority; they might never identify as gay yet nonetheless accept and integrate their same-sex attraction with other domains of their life. Whether youth identify themselves as a sexual minority is less important than acquiring the ability to integrate their sexuality with other essential elements of life. The result is authenticity, peace, and positive social interactions.

Conclusion

The twenty-first century has witnessed a prolific rise in gay youth research and social exposure. The media are increasingly celebrating their culture and characterizing them as they would

any other youth: the girl/boy next door. Charting their development by identifying and describing milestones is one way in which their presence is validated and normalized. It escorts them into the realm of human development rather than the fringes of child development gone awry.

Abstract

High levels of cultural homophobia meant that early research on homophobia in sport did not collect data with sexual minority athletes who were public about their sexuality. However, as homophobia has decreased in Western cultures, there has been a proliferation in research on openly gay athletes. Accordingly, this article investigates the experiences of openly gay male and lesbian athletes in ostensibly heterosexual sports. The authors show that while sport was founded in exclusionary practices, changing cultural norms regarding sexual minorities have extended to sporting cultures.

Early research on homophobia in sport did not collect data with sexual minority athletes who were public about their sexuality (e.g., Messner, 1992; Pronger, 1990); this is for the reason that at the time, openly gay or lesbian athletes were unheard of at collegiate and professional levels of sport (Anderson, 2005). However, in more recent years, as homophobia has decreased in Western cultures (Loftus, 2001; Weeks, 2007), there has been a proliferation in research on openly gay athletes (e.g., Anderson, 2002, 2005). Accordingly, this article investigates the experiences of openly gay male and lesbian athletes in ostensibly heterosexual sports. The authors show that while sport was founded in exclusionary practices, changing cultural norms regarding sexual minorities (particularly for youth) have extended to sporting cultures. Matters are much improved for sexual minorities in sport today in the West, although one recognizes a dearth of research into the experiences of bisexual and transgendered athletes in the West or of sexual minorities more generally in sports in non-Western countries.

Foundation of Sport as a Heteromasculine Preserve

Although there are various purposes of organized, competitive team sport participation in the West, a consistent finding is that sport has served as a social institution organized around the political project of defining certain forms of masculinity as acceptable, while denigrating all others (Messner, 1992; Pronger, 1990). Contact team sports, like American football and rugby, have been recognized as enshrining this politically preferred form of masculinity, where participation is made near-compulsory through boyhood culture (Anderson, 2005; Connell, 1995).

Sport was not always held in such esteem, with a more *laissez-faire* approach before the turn of the twentieth century. In the past, sport was neither compulsory nor culturally valued. While some sport was played, few people had the time, desire, or equipment to play in organized, competitive leagues. The compulsory nature of sport for male youth is instead a product of the fear of feminization of young boys that arose during the turn of the twentieth century (Kimmel, 1996).

There are a number of reasons for this increased focus on sports, including that sport taught boys to become good soldiers as it socialized them into being docile to authority, to sacrifice for the sake of team, that physical fitness was a moral responsibility to society, and to value the greater good (Mangan, 2000; Sage, 1990). These characteristics were also expected behaviors of factory workers, and sport was thus also valued by the owners of industry. However, sport was also valued because it socialized boys into particular, esteemed gendered and sexual identities (Anderson, 2009; Bryson, 1987).

Concerns about gender identity arose partly out of social fears based on Freud's (1905) notion that homosexuality is the product of boyhood socialization into femininity and the absence of a father figure. Given that factory work, much expanded during the second industrial revolution, meant fathers were away from their children for extended periods of time (Cancian, 1987), it was feared that without this masculinizing influence, male youth would grow up to be less attuned to the heterosexuality necessary to produce future workers. Accordingly, in most Western nations, alongside muscular Christianity and the Boy Scouts movement, sport served as a vessel for the indoctrination of young boys into a desire to be associated with heterosexual masculinity (Anderson, 2009; Connell, 1995).

Competitive team sport culture was therefore constructed to reproduce society's gendered and sexual values, myths, and prejudices. Throughout the decades of the twentieth century, no other institution naturalized heterosexual more than competitive sport (Anderson, 2005). As a highly segregated, homophobic, sexist, and misogynistic gender-regime, sport not only contributed to the gender order of men dominating women, but also reproduced a conservative form of heterosexual masculinity that has considerable costs for gay men. This is why women were excluded from sport for so long; women who competed equally alongside men would disrupt the myth of men's athleticism and women's frailty (Burton-Nelson, 1994).

Although male-dominated for much of the twentieth century, women began accessing the institution in the late 1960s, and in the United States, women's sporting participation has rapidly increased since the 1972 passage of Title IX (McDonagh and Pappano, 2008). Today, women are well represented as participants at the lower levels of sport. However, women's representation dramatically decreases in the professional ranks; particularly among the sports that capture media interest (Burstyn, 1999).

Historically, women participating in sport have been subject to homosexual suspicion, in part because of the number of high-profile female athletes who came out as lesbian (Griffin, 1998). However, heterosexual women began also playing sport in large numbers in the 1980s, and their participation began to heterosexualize the sport for women, requiring its participants to boast their heterosexual capital, and silence their lesbian teammates. Even so, matters for openly gay male athletes during the 1980s were far worse. Compared to women, gay men have made very little progress in opening mainstream sports to gay participation (Anderson, 2005; Pronger, 1990) up through this time. Yet by this decade, sport had become institutionalized, even compulsory, within public school systems. It was also this decade that saw the apex of homohysteria in sport.

Homohysteria and Sport

With sport's traditional function of masculinizing and heterosexualizing boys – and subsequently marginalizing effeminacy – it is unsurprising that homophobia and antifemininity have been commonly employed among athletes in the construction of gender-normative performances (Bryson, 1987; Sabo and Panepinto, 1990). This was particularly true of sport (in the Western world) in the 1980s. Here, sport took on renewed importance for boys and young men as it was a central tool in heterosexualizing men in a culture that is labeled as 'homohysteric' (Anderson, 2009, 2011a).

In describing the construction of masculinities, homohysteria refers to a "homosexually-panicked culture in which suspicion (of homosexuality) permeates" (Anderson, 2011a: p. 7). In order for a culture of homohysteria to exist, three factors must coincide: (1) the mass cultural awareness that homosexuality exists as a static sexual orientation within a significant portion of the population; (2) a cultural zeitgeist of disapproval toward homosexuality; and (3) disapproval of men's femininity or women's masculinity, as they are associated with homosexuality.

There are three stages related to homohysteria that a culture (might) move through. The first is prehomohysteria, and the authors suggest this can also be called 'homoerasure.' Here, the culture is extremely homophobic but homosexuality as an identity is effectively erased. Importantly, because the citizenry do not believe that homosexuality exists in the general population, homophobia does not regulate gendered behaviors (although it of course polices sexual behaviors). Exemplifying this, much of the Islamic world today, as well as throughout much of Africa, homosexuality is thought to be 'only' a Western phenomenon (Frank et al., 2010). So while, for example, homophobia is intensely high in Iran, in 2007, President Mahmoud Ahmadinejad claimed that, "…in Iran we don't have homosexuals like in your country." Accordingly, boys in Iran will have less need to distance themselves from cultural suspicion of homosexuality. It is this mass denial that homosexuals exist in large numbers that permits Iranian men to walk together in public holding hands. It is also likely that this prehomohysteric culture will become homohysteric if Western discourses of gay rights are adopted by gay people in those countries.

In contrast, in a homohysteric culture, there is widespread awareness that a significant percentage of the population can be gay and homophobia regulates gendered behaviors. In the United States, homohysteria occurred in the 1980s as the growing visibility of gay people, and a strengthening gay politic contested high levels of homophobia. This was heightened by an increasingly noisy fundamentalist Christianity that was opposed to and demonized homosexuality, alongside the acquired immunodeficiency syndrome epidemic that brought closeted people out of the closet as symptoms of the illness became visible. In this homohysteric, culture boys and young men (particularly those who were unmarried) needed to establish and establish themselves as heterosexual by aligning their gendered behaviors with idealized notions of masculinity. It is especially between the years 1983 and 1993 that boys in Western cultures needed to use sport in order to prove their hetero-masculinity (Pronger, 1990). This is because homosexuality is not readily visible (like gender or race); ostensibly, anyone can be gay (see also Ibson, 2002; Floyd, 2000 for discussion of this).

Given that men's masculinity is/was associated with heterosexuality in Western, industrialized cultures, boys in a culture of homohysteria are/were required to elevate their display of masculinity to prove that they are/were not gay. In other words, they used culturally endorsed sports to distance themselves from being socially perceived as gay. Participation in organized team sports is less important for the construction of heterosexuality in a culture where homosexuality is not believed to exist as a significant demographic of the population.

Because sport has been defined as "the last bastion of male domination" (Burton-Nelson, 1994: p. 6), homohysteria has created a problem not only for effeminate and/or gay men, but also for women. Although women challenge traditional gender boundaries in sport by simply taking part, only certain sports are seen as feminine-appropriate; mainly those that do not require physical contact. Writing specifically about rugby, Wright and Clarke (1999) suggested that women's participation "could therefore be expected to challenge fundamentally what it means to be a male and female" (p. 299). Hence, women playing male-dominated team sports, such as football and rugby, face particular confrontation and questioning about their involvement.

Hargreaves (1994: p. 171) argued that when women participated in male-dominated sports they faced "the greatest criticism and exposure to ridicule." Lenskyj summarized that the central issues concerning women's participation in sport were that, "femininity and heterosexuality (were) seen as incompatible with sporting excellence: either sport made women masculine or sportswomen were masculine from the outset" (Lenskyj, 1986: p. 95).

Griffin (1998) argued that in order to limit controversy about their participation, women have been shown to promote heterosexual (heterosexy) images and use overt homophobia as a way to socially distance themselves from being thought lesbian. The erasure of lesbianism through the promotion of femininity and heterosexuality is known as the 'apologetic.' Felshin (1974) argues that "because women cannot be excluded from sport and have chosen not to reject sport, apologetics develop to account for their sport involvement in the face of its social unacceptability" (p. 36). Davis-Delano et al. (2009) explain that apologetic behavior occurs in numerous

ways: creating a feminine image, or apologizing for on-field behavior, such as aggression (Ezzell, 2009). Even in recent years, Davis-Delano et al. (2009) show that apologetic behavior is still evident; specifically, looking feminine, appearing heterosexual, and apologizing for aggressive behavior.

Even early in the twenty-first century, Cox and Thompson (2001) found that female footballers were assumed to be lesbian because of their choice to play a traditional male team sport. Shire, Brackenridge, et al. (2000) describe the behavior of heterosexual women within one hockey team, saying, "They joked about the lesbian women in order to reinforce their heterosexuality to others" (p. 49).

Accordingly, the conditions described of homohysteria for men in sport also existed for women in sport. Just as a 1980s and 1990s culture of homohysteria presented a problem for both gay and straight men, the homohysteria of women's sport also created a problem for both lesbian and straight women. Women were understood as being pressured into presenting an image of hyperfeminine heterosexuality in order to gain and maintain public support of their new found sporting freedoms (Lenskyj, 2003). The silence and denial of lesbianism in sport permit stereotypes and discrimination to continue unopposed (Krane and Barber, 2003).

Navigating Homohysteria

Since sport has been a homohysteric culture for both men and women at the end of the last century, what does one know about gay men and lesbians who participated in sports during that period? The sheer numbers of lesbians interested in sport did enable their study (e.g., Griffin, 1998). Conversely for men, there is a dearth of research concerning the relationship between sport, masculinities, and homosexuality before the 1980s (see Garner and Smith, 1977 as a notable exception). This is likely because gay athletes had not yet begun to emerge from their sporting closets, nor did they exist openly within the sport-related occupational industry (Anderson, 2005). For example, when Pronger (1990) studied closeted Canadian gay athletes in the late 1980s, he was unable to find men who were out to their teammates. Whether participating in individual sports (e.g., tennis, swimming, and running) or team sports (e.g., football, basketball, and rugby), there were few openly gay athletes in the Western world to design a study around.

Gay male athletes were (and remain) underrepresented in this period for a number of reasons. Anderson (2005) describes the selection hypothesis as gay men avoiding these forms of sport because of their homophobia (Zipp, 2011). However, because most male youth are indoctrinated into sport before awareness of their sexual orientation, it is likely that this hypothesis combines with the silence hypothesis to keep the numbers of openly gay men in sport low.

The silence hypothesis dictates that athletes of the time likely remained closeted because they assumed that the high degree of homophobic discourse, alongside their teammates vocalized opposition to homosexuality, and the high levels of societal homophobia, indicated that they would have a troubled experience coming out (Woog, 1998). Messner (1992) confirmed sport's homophobic disposition: "The extent of homophobia in the sports world is staggering," he wrote. "Boys (in sport) learn early that to be gay, to be suspected of being gay, or even to be unable to prove one's heterosexual status is not acceptable" (p. 34). These attitudes also extended into recreational level sporting leagues, even in liberal cultures. Discussing the Netherlands, Hekma (1998) wrote, "Gay men who are seen as queer and effeminate are granted no space whatsoever in what is generally considered to be a masculine preserve and a macho enterprise" (p. 2).

This paradigmatic view was supported by the quantitative research on university athletes in the United States, too. For example, in 2001, Wolf Wendel, Toma, and Morphew found that white male athletes exhibited disproportionate degrees of homophobia compared to their attitudes toward racial minorities. Hence, sport has been widely recognized as an institution that promotes heterosexuality over homosexuality.

Shifting Intersections of Youth and Homophobia

By the end of the first decade of the twenty-first century, however, studies began reporting a rapidly decreasing level of homophobia among youth (Keleher and Smith, 2012; Kozloski, 2010; Savin-Williams, 2005) even in men's team sports at the collegiate level (Anderson, 2009; McCormack and Anderson, 2010; Southall et al., 2011). Research on British high school students found that heterosexual boys not only espoused progay attitudes, but also condemned homophobia as unacceptable (McCormack, 2012), while this positive generational change had also permeated sport, with openly gay athletes having markedly better experiences than athletes a decade earlier (Anderson, 2011b).

For example, between 1999 and 2002, Anderson (2002) interviewed 26 openly gay high school and university athletes throughout a spectrum of sports in the United States. Due to the attitudes toward gays at the time, finding these athletes required the use of multiple channels. The sample, albeit mostly white, is large enough to say something meaningful about the experiences of openly gay athletes of the time.

The study provided the first examination of the experiences of openly gay male athletes on ostensibly all heterosexual teams. It showed that even without formal exclusion of openly gay athletes from sport, heterosexual athletes within team sports (both contact and noncontact) somewhat resisted the intrusion of openly gay athletes through the creation of a culture of silence around gay identities similar to the US military's expolicy of "don't ask, don't tell" (Britton and Williams, 1995).

Although publicly out, the athletes in this study were victimized by heterosexual hegemony and largely maintained a heteronormative framework by self-silencing their speech, and frequently engaged in heterosexual dialogue with their heterosexual teammates. This is to say that once an athlete came out of the closet, they were met by discourse that basically said "Okay, you're gay. Just keep it to yourself."

In that study, and perhaps unsurprisingly, there were more openly gay runners and swimmers than football or baseball players. Pronger (1990) theorized that competitive team sports that involve collision are more likely to be over representative of macho men, and that gay men might be likely to deselect out of them. Using data from the 1994–95 Longitudinal Adolescent Health Study, Zipp (2011) empirically validates this thesis,

showing that while gay youth played team sports equally with their heterosexual counterparts in middle school, they began to self-select out of team sports by high school.

Of course, it is possible that deeply closeted gay youth play contact sports because of the veneer it offers them against cultural suspicions of homosexuality. There is even evidence to suggest that (back then) many youth intentionally joined macho sports with the ill-informed aim of believing that it would somehow make them straight.

In 2005, Anderson expanded this work on gay male athletes to 40 openly gay and 20 closeted athletes. That study found that openly gay athletes were not physically harassed or bullied, although it was argued that their acceptance was partially attributable to the stigma of homosexuality being downplayed because these were mostly top-performing athletes. Even so, this documented that a split from the past was occurring in sport, with many high school athletes supportive of homosexuality.

Matters have improved significantly in the first decade of the twenty-first century. Supporting this statement, a 27 February, 2006, *Sports Illustrated* magazine poll of 1401 professional team sport athletes showed that the majority would welcome a gay teammate; this included 80% of those in the National Hockey League. Similarly, Cashmore and Cleland (2012) find that 93% of British football fans would be happy with an openly gay player on their team.

Throughout multiple contemporary studies of young men in sport, heterosexual men have been shown to maintain positive attitudes toward gay men in general (Adams, 2011; Cavalier, 2011; Dashper, 2012) and to the possibility of having an openly gay player on their team (Adams, 2011). The same research also showed that decreasing cultural homophobia has a positive impact on athletes' homosocial relations with their straight teammates. Here, heterosexual boys are permitted to engage in an increasing range of behaviors that once led to homosexual suspicion, all without threat to their publicly perceived heterosexual identities (Anderson, 2009; McCormack, 2012).

Collectively, these studies highlight that as cultural homophobia diminishes, it frees heterosexual men to act in more feminine ways without threat to their heterosexual identity. In other words, the homohysteria that so characterized men's sporting participation in the 1980s has dramatically waned (Anderson, 2011b); although homophobia used to be the chief policing mechanism of an orthodox form of masculinity, there no longer remains a strident cultural force to approximate the mandates of one type of homophobic masculinity (see also Floyd, 2000; McCormack and Anderson, 2010).

There is increasing evidence that as cultural homophobia continues to dissipate (particularly among male youth), team sport athletes are coming out in greater numbers. This is clear if one clicks on *Outsports.com*, where hundreds of articles related to openly gay athletes are available. More systematically, Anderson recently documented the positive experiences of 26 openly gay American high school and university athletes (Anderson, 2011b). Compared to the results in the 2002 study, these athletes (who represent the same class and racial demographics) did not fear coming out in the same way or to the same degree as the 2002 athletes. Unlike the men from the 2002 study, they did not fear that their coming out would result in physical hostility, marginalization, or social exclusion (either on or off the field). Athletes in the 2011 cohort were a more diverse group of athletes, too. Not only were team sport athletes represented equally with individual sport athletes, but also excellence on the field was no longer required for acceptance. The men were simply not as good a group of athletes, thus, they were not using sporting capital as a shield against homophobia. Still, these men were widely accepted by their teammates. This study also found that openly gay athletes evade the culture of "don't ask, don't tell" that characterized the experiences of athletes in the 2002 study. Instead, athletes in the 2011 cohort found their sexualities accepted among their teammates. These athletes talked about their sexualities frequently, and none reported that their teammates tried to publicly or privately heterosexualize them. While newspaper and other sources do continue to report high levels of fear concerning coming out in professional sports, it is argued that this is primarily attributable to the attitudes and advice given by key stakeholders in sport (managers and agents) rather than the players themselves.

There are two possible reasons for the improvement of experience of gay athletes. It could be that sport has 'learned' from pioneering openly gay athletes across America; or more likely, cultural homophobia has decreased in the local cultures of the 26 men of the 2011 sample. If the latter is the case, it speaks to a broader decrease in homophobia throughout the country (see Keleher and Smith, 2012). Accordingly, the existence of local cultures with great social inclusivity speaks at some level to inclusivity in the broader culture.

Unfortunately, despite a very large number of lesbian sport scholars, considerably more research needs to be conducted on the experience of openly lesbian athletes in school and community sports today. There has been comparatively very little on the topic since Griffin's (1998) book *Strong Women, Deep Closets*. In few studies that exist, Fink et al. (2012) showed improvements in educational sports for the dozen lesbian women studied, and Drury's (2011) study on lesbian football teams in England shows that, in some cases, sport teams can provide a 'safe zone' for athletes to be open about their sexuality. Melton and Cunningham (2012) also observed that many lesbian athletes of color experienced sexual prejudice and internalized stigma in American university sports; however, they also felt social support from various teammates and, to a limited degree, employees in the sport organization. Finally, Cunningham et al. (in press) observed that lesbian university athletes playing on inclusive, psychologically safe teams were more likely to express their sexual orientation personal identity than were their peers.

Although limited, the research on the experience of lesbian athletes reflects the aforementioned improving attitudes toward homosexuality more broadly. Furthermore, Cunningham (2010) has surveyed nearly 700 university athletic department members in nearly 200 institutions to show that while sexual diversity lags behind age or gender diversity, 54% of the universities studied maintained strong sexual orientation diversity, only 17% showed no diversity.

Future Directions

As cultural homophobia and therefore homohysteria continue to erode in Western countries, future research needs to examine

how this will impact not only upon the lives of self-identified gay and lesbian athletes, but also on that of other sexual and gender minorities. There is a dearth of academic research on the experiences of bisexual athletes (of both sexes) and limited research on the experience of transsexual athletes as well. The experiences of athletes in non-Western countries are particularly problematic, and requires significant research as well. Finally, intersections of sexual and gendered orientations need more examination as they intersect with race.

Abstract

Clifford Geertz's early anthropological studies in Indonesia were conducted as a straightforward ethnographer, although always with a sense of humor. His career-changing sally into Balinese life and the cockfight created a quite new idiom and conceptual apparatus for the understanding of such extravagant excess. His implicit method was that of 'thick description' and he carried this banner into argumentative combat with the predominant schools of quantitative and sternly materialist anthropology. In his classic text *Negara: The Theatre-State in 19th Century Bali* he contends that our understanding of public life is necessarily an interpretation of value and meaning as expressed in the most commonplace of ordinary action. This action embodies 'a constellation of enshrined ideas' where all behavior is symbolic and the drama of everyday life is best grasped as texts to be read. These lessons he sustained by writing some of the best academic prose of his day, demonstrating his precept that humankind interprets as it makes, that human science is one of the humanities and that 'thinking is a moral act.'

I

Clifford Geertz (1926–2006) was not only the leading anthropologist of his generation but, in transforming the subject into his own interpretive idiom while insisting that same idiom be as economical and unaggressive as possible, he summoned the human sciences at large to the common pursuit of true judgment. He brought off this momentous task by giving what he called, in a mind-altering phrase peculiarly his own, 'the blurred genres' of 'the way we think now,' both precision and accessibility. It is fair to add that in so doing he restored more than a little of his country's good name, disfigured as it had become, in Vietnam, Salvador, and elsewhere, by rather too emphatic a view of what was good and bad for other peoples. Geertz taught, by lived example and by explicit doctrine, the best virtues of the American and English literature he knew by heart and which shaped his formation every bit as deeply as the disciplinary conversation of anthropology. It could readily be claimed that, for a season, he made anthropology queen of the sciences, and in so doing gave the intellectual life of his times his signature version of that 'sane, affirmative speech' (W.H. Auden's phrase) without which the social sciences lose sight of their public duty and become the stooges of managerial power.

II

Clifford Geertz's parents were divorced when he was only 3 years old, and he was dispatched into the care of a 60-year-old foster mother whom he called 'Nana,' living out the Great American Depression of the 1930s with her in the hills of northern California, while all the while seeing his parents (who lived into very ripe old age) for a day visit once or twice a year. He went off to a two-room, two-teacher village school with four dozen farmworkers' children and his own, inexplicably intellectual bent, "learning early that 'brightness' was my passport out of exile and into the great world."

At 17, the United States barely 2 years at war, Geertz volunteered for the navy and was allowed in as an electronic technician's mate, repairing radar gear on the USS *St Paul*, sister ship to the much-mourned and unlucky *Indianapolis*, torpedoed in the dark night of 4 August 1945 after delivering the most frightening cargo of the century, the first battle-usable atom bomb, Little Boy, to the US air base in Guam.

As Geertz's own ship steamed onward toward what its crew were braced for as the certain-to-be-terrible invasion of Japan, the bomb was dropped and one of the inventions of the twentieth century for which he and so many intellectuals of the epoch felt the most acute moral disapproval very probably saved his life. It was an early instance of the kind of moral ambivalence, a paid-on-both-sides queasiness, which, over the years, he was to raise into a sort of intellectual principle for his kind of anthropology and the good it might do to others.

On board ship in the empty Pacific, as a friend of his put it, you had all the advantages of suicide and none of the disadvantages. Geertz read all he could get hold of, including the venereal disease manuals ('but the plots tended to repeat'), and played bridge incessantly, warding off the wardroom's stupefying tedium, until he was very good at it, so never touched a card again after demobilization.

He had spent his first 20 years with the kind of oppositions he fashioned into his businesslike, usable, and always generous-hearted schemata: between the agora, the wide-open spaces of familylessness, upstate California in 1929, the hot empty reaches of the *St Paul*, the shimmering blankness of the ocean, and the noisy, crowded racket of a rural school, the close and sweaty din below decks, the packed bunks, and companionways. He took his chances by way of the Navy's natural and colossal wastefulness, his quick wits hitting it off with opportunity. The next, gaping opportunity was the magnificent GI Bill, which provided more or less free college education for all servicemen who wanted it. Geertz's IQ scores were on his naval file; they too had probably helped save his life by switching him into radar and out of direct combat (another useful bit of paying-on-both-sides). They took him to Antioch College, Ohio, to read literature.

Once at Antioch he continued the tumultuous reading with which he had filled the vast blanks of life in the Pacific, and found American literature of the twentieth century as crowded

and exhilarating as he could wish, taking particularly keen and comradely pleasure in the sumptuousness of Wallace Stevens, the heavy historicizing of the action in Faulkner, and, a little later, the hilarity of Saul Bellow, together with the wry, delightful difficulty of James Merrill. His guide at Antioch through this busy, noisy throng was one George Geiger, a great name in the subject and a teacher who not only cultivated Geertz's terrific eye for the comedy of human nature but, at the same time as introducing him to contemporary philosophy, then at the height of its proselytizing for minute attention to linguistic particularity, warned Geertz off such study when he looked forward to postgraduate work.

Geiger advised his brilliant pupil that this philosophy, however acute, was too far from the facts of life and the irresistible messiness of everyday human endeavor. With a shrewd sense of his student's character as well as an accurate judgment as to the then most thriving subject-matter in human inquiry, he directed Geertz to Harvard's Department of Social Relations to which the anthropologist Clyde Kluckhohn introduced him and to its boss, Talcott Parsons, whose ambition was to crown sociology, not anthropology, queen of the human sciences by way of a crazily inclusive Theory of Everything, in two volumes entitled *The Structure of Social Action*, (Glencoe: the Free Press, 1937 and 1951.) and *The Social System*.

Such ambitions had little place in the view of the world, Geertz contrived for himself out of a personal experience compounded of solitary self-sufficiency, an exceptionally lively sense of humor, and the pragmatic cast of mind, at once doctrinal and characteristic, of a quiet and talkative American. His ideal type came not to cajole other people into the American way of life, but rather to comprehend the sheer variety of humankind as no more and no less than the polyglot, technicolor materials out of which his own nation was made.

III

Building himself a method and a style out of a character and its dispositions, he turned back in a way then unexpected to the canons of contemporary philosophy. From J.L. Austin (1962) he took the contention that language is not an endless sequence of true, false, or meaningless propositions, as A.J. Ayer would have it (Ayer, 1936). Rather, it is an unstoppable business of making and doing and instituting; speech and writing was, in Austin's neologism, *performative* and actively worldmaking.

Beside Austin, Geertz placed Gilbert Ryle's *The Concept of Mind*, in which he found the bracing argument that there is no such thing as 'a ghost in the machine,' which is to say that each of us does not have a 'real' 'inner' person much truer and more important than the 'outer' creature other people see. Each of us is constituted by our daily actions, including our speech, for everyone else to see and hear. From Ryle, Geertz also took a key slogan, 'thick description,' which he turned, in one of his most gripping and inclusive essays, into the first principle of ethnographic practice: "Analysis … is sorting out the structures of signification … and determining their social ground and import" (Geertz, 1975). 'Thick description' is a matter of telling the truths observed, for sure, but telling them by way of all that is going on in human encounters, layers of it, subjunctive piled on indicative, hints hidden in flagrancies.

Lastly, Geertz's architecture, only fully constructed, in its finished form, by the time he became Professor (and Head) of Social Science at the Institute for Advanced Study, Princeton, rested upon an American literary critic of a sort-of-Marxist persuasion, Kenneth Burke along with, clinchingly, the great iconoclast of philosophy, Ludwig Wittgenstein in his second incarnation as philosopher of everyday language.

Psychological or emotional words do not, Wittgenstein told him, name private experiences which we alone can know. The language of feeling is what teaches us to differentiate emotions and makes it possible, from infancy forward, to distinguish them from raw sensations. We learn the rules of feeling according to what Wittgenstein famously described as the language-games of social practice, and we can only make ourselves understood (including to ourselves) if we follow the rules. "Ideas are not," as Geertz himself puts it, invoking Wittgenstein, "and have not been for some time, unobservable mental stuff. They are envehicled meanings …," (Geertz, 1980) and the vehicle may be the usual signs of language, as monologue, tête-à-tête, or tumult, or they may be stylized symbolic actions – rituals, ceremonies, legal disputes, religious meditation, scientific experiment, childbirth, deathbed.

Wittgenstein gave Geertz the key to unlock the significance of commonplace signification, and enabled him to say, in one of his grandest aphorisms (their occasional grandeur in no way affecting their careful domesticity and localism), made in this case about Balinese ceremony,

> The real is as imagined as the imaginary … The dramas of the theatre state, mimetic of themselves, were, in the end, neither illusions nor lies, neither sleight-of-hand nor make-believe. They were what there was.
>
> *Negara*: p. 136

This is a mature formulation of the idea found in Kenneth Burke 30 years previously. 'Dramatism' is the second of his key concepts (the first being Wittgensteinian), and Geertz found and endorsed it in Burke. If language is a "symbolic means of inducing cooperation in beings that by nature respond to symbols," then the "dancing of an attitude," which is a particular symbolic action, is held in the larger plot of the social drama. Nor is this use of drama, in Burke's eyes, metaphorical. "Drama is employed *not as a metaphor* but *as a fixed term* that helps us discover what the implications of the terms 'act' and 'person' really are" (my italics).

Geertz, as one would expect, fairly delighted in the phrase "the dancing of an attitude," and was glad to endorse Burke's fundamentally comic view of human action where 'comic' connotes not merely all there is in people's conduct to make you laugh, but an inclusiveness of vision taking in, according to Burke's definition, (This quotation from Kenneth Burke. In: Gusfield, J.R. (Ed.), On Symbols and Society. Chicago, University of Chicago Press, pp. 135–138.) "The maximum of forensic complexity." It encompasses human misery and cruelty by seeing their operation not as tragic but either as mistakes or as shameless acts of cheating. By this token, politics is all culture, and "ideology is to myth as rhetoric is to poetry" (Burke, *Ideology and Myth*', Kenneth Burke. In: Gusfield, J.R. (Ed.), On Symbols and Society. Chicago, University of Chicago Press, p. 303).

IV

Geertz, naturally, only shook these readings into theoretic order gradually, and as his career led him far east, to Java and Indonesia in 1952, where the Dutch were disencumbering themselves of the White Man's Burden, and the universities of Harvard and Chicago, under whose auspices Geertz and his wife Hildred were traveling, were busying themselves, with government aid, in devising forms of inquiry which would be good for new nations, and keep them away from dabbling in communism.

The Javanese themselves had more violent and disputatious plans for new nationhood, and Geertz spent his almost 20 years (1952–71) of regular but necessarily intermittent fieldwork with a background (mostly) and foreground (sometimes) of murderous civil war. He wrote his four books on Indonesia out of these bloodstained passages, finding, in particular while writing *The Social History of an Indonesian Town* (the town in question being Pare disguised as Modjukoto) and *Agricultural Involution* (The first published by MIT Press, Cambridge, MA, 1965; the second by University of California, Berkeley, 1963. *Peddlers and Princes* from Chicago in 1963.) ('involution' being for Geertz an unmodern variant of modernity in which an old ecology is forced to accommodate new and impossible overcrowdings of agricultural production) that hypothesis-testing was no sort of method, and that daily life went unrepentantly on even with tanks in the street and corpses hanging from telegraph poles. Out of these clashing disparities he fashioned his daring interpretations of symbolic action, *Peddlers and Princes* giving space to his old novel-writing ambitions by way of a boisterous cast of historical heroes each retaining busy actuality in the present, and *The Religion of Java*, the major work of the two decades and an early compendium of symbolic anthropologizing in the accents of Max Weber, leveling old Muslim theodicy at new capitalist economics.

During 1957 Geertz opened his long, loving, and horrified relationship with Bali, and, 'malarial and diffident,' attended the cockfight which provided the occasion for Geertz's most famous contribution to the literature of anthropology as well as being itself a striking addition to English literature *tout court*.

The cockfight was then illegal in Bali, but everywhere practiced. Two eagerly living, not insubstantial creatures rip each other to bits with razors fastened to their heels. The illegality, the smell of blood and violent death, the likelihood of a bust by the cops, the implicit, inescapable jokes about men's cocks and cockfighting (but, by God, the dead seriousness of both), the noisy, excited, dusty gregariousness of it all, gives the traveler's tale terrific vitality, a whiff of prurience, and an object lesson.

The cockfight is duly raided by the police, the Geertzes run for cover like everyone else, are shielded by complete strangers, and are thereafter one of the family, getting to see plenty of cockfighting, cocktending, cocknurture, cockworship.

Crucial to an understanding of the cockfight is how utterly unlike everyday Balinese decorum the crazily abandoned behavior of the fight itself is. Animality to the Balinese is obscene, cockfights dramatize beastliness with shocking immediacy. As with all sports, there are intricate divisions of labor and indispensable experts – spurriers, handlers, umpires, and of course holders of the betting ring. The passion of gambling, the smell of blood, the flutter of torn feathers, the commitment of the (male) self, the rivalry of owners and villages and of mutual standing, catch up in a single whirl of good luck and bad the same mighty themes as do.

> … for other peoples with other temperaments *King Lear* and *Crime and Punishment* – death, masculinity, rage, pride, loss, beneficence, chance – and, ordering them into an encompassing structure, presents them in such a way as to throw into relief a particular view of their essential nature.

It is a bit of a shock to see Shakespeare and Dostoevsky put so coolly beside the fighting cocks. It is meant to be. Geertz uses anthropology's licence to be cavalier with categories. Art is both systemic across cultures and utterly peculiar to cultures. Its first use is

> … to render ordinary everyday experience comprehensible by presenting it in terms of acts and objects which have had their practical consequences removed and been … raised to …, the level of sheer appearances.

Art forms are first of all a way of theorizing life without paying in blood or money (or, in the case of gambling, not too much money). You may pay in tears, at the cockfight or at *La Traviata*, but not for long. Art gives form to a story about ourselves in which we can try out how things might have been otherwise if only we had been or had met the heroine in the movie or the novel.

In the case of the cockfight as Geertz interprets it for us (and for the Balinese also), a people of unusual blandness and obliquity in ordinary dealings present a tale of themselves as wildly clamorous and murderously cruel. Like poems and symphonies, the cockfight is all passion and melodrama, and the gambler-spectators as well as the gambler-owners throw themselves into the fight with the grand gestures of Guignol, the masks of comedy and tragedy. What tragic actor, symphony conductor, and concerto pianist perform for us, they perform, with a little help from their cocks, for themselves.

Thus cockfights, puppet plays, renaissance frescos, football matches, television drama alike present aspects of a people's subjectivity to itself, divided according to the groups and classes who use the form and the contents in question. That particular corner of the subjectivity may be dusty and unvisited or familiar and well swept, but in *recognizing* it as a place for the moment to be, the audience not only view themselves, they remake themselves as well. The forms and contents of our cultural lives, heavy with feeling, are part of our constitution in all senses of the word.

In the case of the Balinese, as in all other cases, the game is played within the thick, deep and taken-for-granted habitations and habiliments which make the plays what they are. Cockfights are, of course, for men only and not any men but those with the status and the money to go in and play deep (lose from the depths of those same pockets also, if need be), as the eponym of Geertz's title (taken, surprisingly, from Bentham) indicates.

Geertz places the betting structure isomorphically upon the social structure and the evenness of the fight. That it fits both

so well is testimony to its significance. As a matter of making categorical mischief – the anthropologist's contrastive–comparative business being with understanding the cultural forms of others by way of a deliberate misprision of one's own (*King Lear* and the cockfight) – Geertz levels the works of high European literature with low Balinese birds.

Like all good ethnography it carries a sting in its tale, a tale told by the Balinese to themselves. It is in this essay that Geertz most plainly teaches his methodological lesson that the present-day human scientist is, in his or her puzzles and epiphanies, much more like a literary critic, an art historian or a jurisprudentialist than like a mechanic ('how does this work?'), an anatomical surgeon ('scalpel, please') or even a cryptographer ('E means P'). The shadow play, the funerary rite, the cockfight and, in a moment, the bazaar bargaining in Sefrou are ways of living-and-telling stories of ourselves and their selves to us and them. All social institutions and cultural forms are imaginatively embodied works, graspable by anybody who takes enough trouble. Towns have symbolic forms as much as marriage ceremonies, mortgage agreements, election campaigns, and poems. Each is turned to particular purposes; each "[puts] emotion to cognitive ends"; each is a thread woven into the dense tapestry of social narratives which is our definition of a culture.

V

The admission of the Balinese cockfight to the disciplinary canon was unstoppable and right. But it briefly obscures a disciplinary principle at the heart of Geertz's *oeuvre*. He quotes but then sidesteps a remark of George Santayana to the effect that "people compare when they can't get to the root of the matter," but comparing unalike conduct and its latent symbolism became for Geertz the very mode of his vision. A casual acquaintance had suggested Morocco for the other half of his bifocal method – 'it is safe, dry, Muslim, and the food is good' – and Geertz intended to dramatize his comparativism by using the optic he had cut to look at Java as a lens for looking at the market town of Sefrou tucked beneath the Atlas mountains. It was a jostling, argumentative, thronged, and sufficiently peaceable place packed with Berbers, Arabs, Jews, Quranic teachers; with shepherds, sheikhs, imams; the spacious market-place and the 600 small shops in the narrow streets round about jammed with sociable tea-and-coffee drinking, cheroot-smoking bargain-makers.

This *suq* was his subject, and with a small team of colleagues including his first wife, Hildred, Geertz pursued Meaning and Order in Moroccan Society (With Hildred Geertz and Lawrence Rosen and a photographic essay by Paul Hyman, Cambridge University Press, New York, 1979.) over many visits and 7 years, discovering those crucial values firmly established in a baffling whirl of linguistically defined genealogy (the *nisba*), the economic and physical immediacy of the church (*habus* and *zania*, tithe and college of worship), the density of market life (*suq*) and the completeness with which its frequenters (*suwwaq*) disappear into that life.

There *is* order in all this, and any amount of meaning. (The predicament for the modern world is that as the density of this kind of local life is dislimned, meaning begins to make itself scarce.) But there is no Lévi-Straussian bipolarity nor Leachian algebra nor Douglasian quadrant which will allocate and clarify it. Such sorting may *always* be attempted with the incorrigible messiness of human societies, but binary patterns or quadrant allocation are more likely than not to lift life up into the upper air of abstraction and to deprive the unbearable lightness of human beings of the heavy weighing down so blessedly provided by custom, practice, and locality.

The comparative, bifocal, astigmatic vision which is Geertz's prime contribution not just to his parent discipline but to our common understanding of (in the blank phrase) the modern world, everywhere insists upon the endless, contradictory minuteness of social conduct, coexistence of quite incompatible beliefs and practices in its members, the many contexts.

> … within which men [this is Morocco in the 70s, after all] are separated by their dissimilitudes and those … where, however warily and however conditionally, men are connected by their differences.
>
> *Meaning and Order*: p. 141

The moral lesson he was never tired of repeating – *had* to repeat so often because his listeners were deaf to it – is the Wittgensteinian one that there is no such thing as a private language. Inner life is visible and audible in outer action. The 'Moroccan mind,' like any other mind, "is an overt, observable feature of a well-lit public arena in Moroccan society" (*Meaning and Order*: p. 212).

To drive this lesson home, he then turned to a radically historical example once more to show (noting in a pungent dictum on the way, that 'examples instruct, they do not prove') that the public drama of life is eloquent of the deepest meanings of the society in question (not of the whole world, that is, but, in this case, of the Balinese people, which is quite enough to be going on with).

Negara: The Theatre-State in 19th Century Bali (Princeton University Press, Princeton, 1980.) is Geertz's single and most complete masterpiece. It describes, and interprets by describing, how a society mad about status, scrupulous in husbandry, frequent, brief and severe in battle, gorgeously elaborate in its many lavish forms of cultural expression, ordered its rulers, its pageants, and the cultivation of its rice paddies into its long-perpetuated 'theater state.'

This is political theory all right, but far away from what Geertz calls "those great beast views of the state that, from Hobbes … to de Jouvenal … locate its power in its threat to harm." He goes on to admonish those who, with Marx or Pareto in hand, see the show of state, its semiotics and public spectaculars as mere devices with which to adorn itself in legitimacy. There is a good deal of sanctimony in the zeal with which political theorists point out the presence of power, with "coercion its expression, violence its foundation, and domination its aim," (*Negara*: p. 134.) but "such tired commonplaces … put out of sight all that is important and interesting about politics." They are blind to its drama, to the forms, rituals, and conventions which hold a whole society in its place. The Negara did the job for the Balinese for seven whole centuries before the Dutch took slaughterously over. The question then for us, readers of Geertz's wholly exotic and very tall, detailed, and actualized tale, is what are the dramas which

command our own allegiance? "For the [Balinese] pageants were not mere aesthetic embellishments, celebrations of a domination independently existing: they were the thing itself." (*Negara*: p. 122.)

Geertz compresses the theater-state into a complex model, holding in a tense equipoise and without remainder the 'high gorgeousness' of pagoda and palace, processions and cremations (sumptuously described in his historical source) together with the practical arrangements for smallholding, irrigation, and ensuring the staff of life, the rice crops.

In the Bali of Geertz's figuration the model of the state is all-inclusive; neither culture nor society leaks out anywhere. The drastic, implied challenge to political scientists in (to go no further) the United States, is then to match Geertz's style of metaphor with a comparable (but of course unalike) dramatization of, over here, the top-heavy ceremonies of public statements outside the White House and, over there, the erratic disjunctions of political-life-as-televised and then responded-to in Tennessee and Montana.

VI

After *Negara*, which came out in 1980, Geertz more or less finished with fieldwork. Within the discipline, he was much beset by a new generation tormenting itself about the past complicity of American social science in continued imperialist adventures of a bloodthirsty, anticommunist kind, whether in Columbia, Chile, or Vietnam. This self-torment frequently declared itself as a sort of *angst-de-politesse* about whether the fieldworker condescended to, overrode the self-explications of, or otherwise abused the subject-and-object of inquiry.

The *angst* in question is most readily to be seen in the title of a revisionist study of Geertz's own territory, John Pemberton's *On the Subject of 'Java,'* praised at that date by another youngish Turk, Benedict Anderson, as 'a brilliantly Derridan ethnography' (Derrida being the all-purpose authority for putting everyone's understanding of other people in the inverted commas of self-delusion). Geertz would have none of this; it was 'moral hypochondria.' He set himself, in a series of gripping essays – each one, it should be added, a model of the best Anglo-American prose of his day – consistently to enumerate the principles of his very own 'blurred genre.' 'The way we think now' should be couched in a humane and commonly intelligible language with which to write (the title of another of his canonical essays) "the social history of the moral imagination." (In his second collection, *Local Knowledge: Further Essays in Interpretive Anthropology*. Basic Books, New York, 1983.)

From his spacious, egalitarian purview in the Chair at the Institute for Advanced Study, he assembled his doctrinal version of modern letters, fluent, talkative certainly, prompt with a succession of memorable aphorisms, unfailingly funny, wise also, one best face and manner of his nation. In his classic memoir, *After the Fact*, (*After the Fact: Two Countries, Four Decades, One Anthropologist* (Harvard University Press, Cambridge, MA, 1995); *Works and Lives: the anthropologist as author* (Polity Press, Cambridge, 1988).) with its James Thurber-punning title ("I'm just trying to creep up on it"), he surveys his own work; in *Works and Lives* he surveys that of his masters, mistresses, and equals (with particular affection, Margaret Mead); in *Available Light* (a typical title) (Geertz, 2000) he tours the terrain of the way we think now with a habitual emphasis on, as one essay title has it, "thinking as a moral act" – which goes on, relevantly, "ethical dimensions of anthropological fieldwork in the new states."

The collection, it is much to the point of this coda to add, was given to worldwide audiences, often in those many Institutes of Advanced Study made in the image of the great original at Princeton: in Florence, the Netherlands, Berlin, Vienna, and under the aegis of the tanner lectures.

The final essay betokens this large purview. It is called "The World in Pieces" and asks of us all, "what is a country if it is not a nation?" It commands by example Geertz's mode of thought as refusing "intensely generalised reflection on intensely generalised matters" commending instead an intellectual activity 'mobile, exact, and realistic' – well, yes – a kind of thought taking to heart all he has had to say about the necessity of local knowledge, the jarring coexistence of modernity and antiquity in all our lives, the utter unamenability of new nations to old power, all this and our "deepest and most central commitment; the moral obligation to hope" (*Available Light*: p. 260).

Geist (Spirit): History of the Concept

Eric R Lybeck, Girton College, University of Cambridge, Cambridge, UK

Abstract

In the century before the 'Classical' period of social science, a number of modes of scholarship made use of the concept of *Geist* – translated in English as 'Spirit' or 'Mind.' The concept was relational, and connected the universal and particular in an organic unity. This article traces the history of the concept from its origins in Christian theology to Montesquieu's *Spirit of the Laws*. Later applications in German philosophy included Herder's nationalism and Hegel's dialectical idealism. The concept had direct influence on the historical legal sciences until falling into disrepute as a result of application in spiritualism and Nazi ideology.

Introduction

Early in his classic essay, Max Weber asked the reader's forgiveness for using 'the somewhat pretentious sounding' expression 'Spirit of Capitalism' (Weber, 2002: p. 8). He then explained that his object of study could not be defined, but only illustrated. To that end, he referenced Benjamin Franklin's words embodying this "ethically slanted maxim for the conduct of life" (Weber, 2002: p. 11). No one doubts the influence of Weber's *Protestant Ethic and the Spirit of Capitalism*'s influence on the social sciences. Yet, few today recognize that Weber's use of the term 'spirit,' or '*Geist*' in the original German was not of his own invention. Rather, within the legal sciences in which Weber was trained, the term was a technical concept characteristic of his Age. To grasp this usage, we must reconstruct the context in which the concept was situated.

Unfortunately, though widely used throughout the nineteenth century, '*Geist*' did not have a clear-cut conceptual definition, translatable across different disciplines or authors employing the term. The word reflects a disparate set of meanings – sometimes referring to a specific object of study in cultural studies, and sometime to the totality of the cosmos. The complex definitional constellation in the German language, where the term was employed most regularly, is reflected in the difficulty of translating '*Geist*' into English. The three most widely used translations are 'Spirit,' 'Mind,' or 'Ghost.' The last is etymologically closest, reflecting the Germanic origins of English. However, in academic texts, 'Spirit' and 'Mind' are more frequently employed. In other instances, as in, *Zeitgeist* – literally, the spirit of the age – the term is left as is.

This summary conceptual history will not provide a firm definition, but rather traces the historical development of a wide set of usages that the term has engendered during the modern period. Just as Weber could not define the particular spirit of capitalism, but only describe it, so too will this history of the conceptual usage of '*Geist*' provide illustration of the meaning for those who used it.

Origins of the Term

Theology: The Holy Ghost

Over the course of the modern era, particularly since the eighteenth century, the concept of spirit took on secular connotations. But these origins were prefigured by the use of the term in Theology. The notion of the Holy Spirit had substantive import within Christian religious conceptions of the relationship between God and humanity. A comprehensive history of theological interpretations of the Holy Spirit exceeds present purposes, but we might begin by noting the change that occurred during the Protestant Reformation. Traditional church doctrine had established that the Holy Spirit was the mediating force between humans and God. However, Protestantism grounded this relationship within the individual, rather than in the institution of the church and its hierarchy. In John Wesley's Methodism, for example, the Spirit reflected 'holiness' and 'love,' which was embodied in the individual before he or she noticed it. By recognizing this Spirit in themselves – not through scholarly exegesis, but through faith, love, and deeds – the faithful converted their lives into one in accord with God's will. The separation between God and Man was mediated by the Spirit, so the elected came to see herself as enacting the will of God through her worldly action.

This brief illustration of the meaning of Spirit in Christian theology highlights several aspects retained in the secularized concept. First, Spirit is relational. Though there are two realms of experience – human and divine – the Holy Spirit mediates between the two. Second, Spirit is particularistic, while remaining universal. No contradiction between part and whole adheres precisely because the individual and God are mutually related through Spirit. Finally, the Christian encounters the Holy Ghost through nonrational experience irreducible to logical form or cognitive effort. Spirit is felt, not thought.

Montesquieu's *The Spirit of the Laws*

Though some aspects of the theological notions of spirit were retained, the term was secularized and grounded further within the mundane, human realm during the eighteenth and nineteenth centuries. The most influential source of this development was certainly Baron de Montesquieu's *De l'esprit des lois (The Spirit of the Laws)* (1989). As Raymond Aron (1998) noted, Montesquieu can be considered the father of modern social science insofar as his aim was "to analyze and to comprehend the social as such, both as element and as entity" (Aron, 1998: p. 10). *The Spirit of the Laws* reflected a revolution in legal writing, providing the lay reader access to the logic of given modalities of law, while adding a novel demonstration of law's fundamentally relational character. Various environmental

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03120-2

particularities, including climate, size, population, wealth, trade, manners, and custom, were essential conditioning factors in the function of different laws. These related environments particularized the function of law within given territories and societies. On one hand, the spirit of the law refers to the sum totality of all the relations of law to other elements. On the other hand, the 'general spirit, moral, and customs of a Nation' represents one essential element itself (Montesquieu, 1989: bk. XIX). This general spirit prepares people's minds to receive the best laws, thereby delimiting the possibility of wholesale overhaul of the law. To change the law, one must first address the spirit in which the laws are to be situated.

As a foundational Enlightenment text, *The Spirit of the Laws* contributed to a *trans*-European conceptualization of a spirit which lay behind and through the laws and practices of given societies. The spirit was no longer that of God, but a quality and product of the people themselves. Though, of course, influential in his native France, Montesquieu's influence was felt most firmly in England, as in Edmund Burke's conservatism, or in Sir Henry Maine's comparative legal scholarship. Appreciating the Frenchman's valorization of English institutions, Burke also asserted the priority of historical tradition which limited the possibility (or ethical validity) of wholesale political revolution outside the peaceful evolution of the customs, practices, and beliefs of a people. Similarly, Maine's comparative investigation of the historical shift from status-based to contract-based societies would have been inconceivable without Montesquieu's revelation of an object, 'spirit,' which historically prefigured emergent, positive laws.

Nation and Spirit in Romantic Germany

The history of the concept of *Geist* in Germany is part and parcel of the development of idealist philosophy, and therefore can begin with Immanuel Kant's posing of the question: how is valid knowledge possible? However, Kant's program was primarily epistemological, and it was through the rejection of his formalistic, systemic account of knowledge that future idealist philosophers developed their various notions of Spirit. These early criticisms of Kantian epistemology moved, generally, from the level of cognition toward that of experience. Relinquishing the primacy of the transcendental subject encouraged substantive inclusion of history, which was traceable to the spirit of the time or people. Furthermore, the dualisms and formalism of Kant's schemas tended to be contrasted against the organic unity of reality and humanity. The resulting Romantic notion of *Geist*, in a sense, stood as a place holder for this relational, experiential, nonrational unity.

These Romantic counterpositions were not univocal and developed in various directions. Again, this multiplicity is reflected in the numerous connotations the term, *Geist*, obtains in German thought. One line of conceptual development can be traced within idealism itself, leading from Kant to Fichte to Schelling to Hegel. Another can be read in parallel, which includes the hermeneutics of Herder, whose influence on legal science and history was perhaps most significant. Following the initial flourishing of idealism in Germany, however, intellectual trends, including materialism, positivism, empiricism, utilitarianism, and Darwinism, led the term into temporary disrepute until Wilhelm Dilthey recovered the 'science of spirit' '*Geisteswissenschaft*' in the late nineteenth century. It is important to recall the overlapping discursive contexts of the term's usage.

To Hegel

Since the dense history of philosophical idealism cannot be condensed easily, a summary of the line from Fichte to Schelling to Hegel can serve as a point of arrival at the high watermark for the role of *Geist* in German thought.

Johann Gottlieb Fichte was the first to take the inaccessible 'thing-in-itself' from Kant's noumenal realm to human consciousness itself, asserting the knowing subject becomes truly and authentically *Geist* in the course of wilful activity. Rather than subjective consciousness contrasted against an objective 'real,' Fichte recognized the intersubjectivity of self-consciousness accessible through human action.

Friedrich Schelling further extended Kant's observation that the world must be organized in a way that allowed consciousness access to reality to develop a natural philosophy in which the ideal springs from the real. The world becomes one of the ineffable experience and feeling. In contrast to the scientific knowledge given primacy by Kant and the Enlightenment, the Romantic world of Nature becomes the ultimate site of truth.

Hegel's philosophical system represents the synthesis of the three positions of Kant, Fichte, and Schelling. In *The Phenomenology of Spirit*, he criticized Kant's formal system as a synoptic index – 'like a skeleton with tickets stuck all over it' – which loses connection to living reality (Hegel, 1967: p. 110). Schelling's Romantic alternative vision of an Absolute world of sensation and feeling proves no solution as Kant's bright noonday light becomes "a night in which all cows are black" (Hegel, 1967: p. 79). Mediating between the two extremes, Hegel extended Fichte's emphasis on self-consciousness by positioning the emergence of reflexivity within a historical trajectory of the Absolute Idea. Over time, the Absolute has developed the means through which it can finally become conscious of itself.

Hegel's synthesis extends Schelling's Idea as objectively encountered in Nature. And yet, reality is always being *realized* through an objective process moving teleologically toward higher levels of self-knowledge. Idealist philosophy has provided the basis upon which Spirit now recognizes itself as "the grandest conception of all, and one which is due to modern times and its religion. Spirit is alone Reality. It is the inner being of the world" (Hegel, 1967: p. 86).

Hegel introduced his conception of *Geist* in *The Phenomenology of Spirit* completed in 1806 at the very moment French Revolutionary forces entered his home town of Jena. Indeed, Hegel described Napoleon Bonaparte as the World-Spirit (*Weltgeist*) on horseback. As the embodiment of the concrete universal, Napoleon, like other great men of history, realized objectively the unfolding Absolute. This social philosophy of history is revisited within the *Philosophy of Right* written in 1821. The State is objectified spirit for Hegel, which is achieved to the extent social freedom is actualized in law. Coercive prohibitions allow individuals to go about their business without

interference, while the law reflects the morals and will of the people. The citizen confronts the State as an ordered, objectified Idea, which is rational, not in a formal logical sense, but rather as dialectic moving through the spiral of historical trajectories and higher planes of integration.

Hegel's political theory obtained an immense influence within the Prussian state during the *Vormärz* (pre-1848) period. His conception of the State as the objective embodiment of the World-Spirit provided conservative justification for the status-quo and the ultimate authority of civil servants, like himself as professor of philosophy at the University of Berlin.

To the German Historical School

Hegel's philosophical system certainly provided the most prominent use of the term, *Geist*. Yet, other related scholars and discourses developed the term in directions that limited the concept in such a way as to ground the object in society, language, and culture, thereby encouraging the treatment of spirit through social science. Indeed, scholarly attention to spirit can be seen to be the very source of the emergence and proliferation of social science in German academia, beginning especially within the historical legal sciences of Friedrich Carl von Savigny and Jacob Grimm.

Before encountering the German Historical School's recognizably social scientific, empirical, and historical treatment of societies, we must step back to revisit the hermeneutic inspiration provided especially by Johann Gottfried Herder's concept of '*Volksgeist*.' Indeed, Herder should be read as the most important theorist of Spirit since even Hegel's broader conception was, in part, inspired by the earlier theologian. In 1769, Herder coined the term '*Zeitgeist*,' defined as the general cultural, intellectual, ethical, spiritual, and political climate of a given era. This reflected Herder's essential role as midwife of history, which thoroughly penetrated German consciousness in years to come. And, just as *Zeitgeist* cast, the general spirit in diachronic time, the term, *Volksgeist*, defined as 'national culture,' grounded the overall climate of particular cultures and peoples in territorial space.

Later commentators have seen Herder as a source of racial thinking insofar as particular groups' national character and history are determined by their 'nature' and 'heredity.' There is certainly merit in this interpretation, especially in light of later inspiration drawn by National Socialists and other racist ideologies. However, Herder's conception of the *Volk* was a suprabiological category. Spirit was grounded, not in blood or physical attributes but in culture and language; a unique manifestation of groups and societies reflected in "dress, food, customs, domestic economy, arts, and amusements" (Herder, 1803: p. 8). Thus, Herder was among the first proponents of cultural studies and anthropology.

The *Volksgeist* is 'natural' in that it engenders a real and constraining force upon the development and character of nations and their citizens – connecting all classes and subgroups into one community. Herder provided an original theory of nationalism from which later modern forms derived – a vision of a unified German spirit nearly a century before a united German empire came into legal existence in 1871.

Herder's philosophy of history moved in the direction of social science when Friedrich Carl von Savigny produced an influential pamphlet titled *Vom Beruf unserer Zeit für Gesetzgebung und Rechtswissenschaft (On the Vocation of our Age for Legislation)* (Savigny, 2002) during the course of a debate over legal codification with the jurist Anton Friedrich Thibaut in 1814. The document would become the foundation of the German Historical School of Law. Savigny suggested that the law was derived from the *Volksgeist* (spirit) of the population; the result of custom, language, and the particularities of the 'nation' from which the law emerged. At the same time, an internal, organic drive compelled the evolution of law according to 'silently operating powers' (Reimann, 1989). In contrast to the formalism and positivism of Thibaud's projected codification project, Savigny insisted that too little was known of the actual cultural spirit of the German people. Without precluding the possibility of codification in the future, the task of a realistic historical jurisprudence managed by trained legal scientists was a necessary precondition for successful legislation.

Savigny separated the study of legal science into two modes – the systematic and the historical. With reference to the Roman *Institutiones* collated during the sixth century CE reign of Justinian I, Savigny argued for the systematic treatment of the abstract relations between laws and civilization. However, equally essential was historical analysis of the particularities of the *Geist* at different times and places. The historical school Savigny inaugurated became consolidated around the *Zeitschrift für geschichtliche Rechtswissenschaft* founded in 1815 with Karl Eichhorn and Johann Göschen. Though Savigny, like Hegel, was criticized in 1848 as a spokesman of the conservative forces of the *Vormärz* period, the *Zeitschrift* had been one of the primary vehicles for political criticism during a period of radical censorship in German lands as a result of Metternich's Carlsbad Decrees. Embedded within the arcana of Roman historical detail were indirect claims for ideal constitutional reform. Though presented as the objective description of historical fact, legal science was a Trojan horse for political science and normative political theory. Romanist scholars, like Savigny and Berthold Niebuhr, focused on the ideal freedom obtained in the early Roman Republic, contrasted against the conflict and chaos of the later Empire. In so many words, liberal Republicanism for Germany was projected on and through historical Roman images. All the while, the conservative influences of Montesquieu, Burke, Herder, and Hegel came through insofar as no revolution was projected; rather, careful thoughtful evolutionary reform according to tradition and national spirit.

A second wing of the legal science movement dedicated attention to scholarship into existing German culture itself. Through the work of Eichhorn and especially Jacob Grimm, who collected the folktales and customs of German villagers with his brother, an image of the German *Geist* was obtained and interpreted by the Germanists. Images of the *Gemeinwesen*, or, civil community, were constructed out of the etymological and philological interpretation of symbols in faerie tales. For example, Grimm traced the legal concept of *Lösegeld* (compensation in tort claims) to the archaic form of the word 'Otter,' thereby connecting to a story of a hunter who infringes upon the property rights of farmer whose son had transformed into an otter (Crosby, 2008: p. 112). Similarly, the familiar Cinderella story of the glass slipper should be understood in

terms of the custom of the groom fitting a shoe on his virgin bride as a symbol of property ownership exhibited before the community. Grimm and his liberal legal scientific colleagues sought enshrinement of these traditional customs in the rapidly developing German legal apparatus, which they often perceived as aristocratic, elitist, and overly rationalist, in contrast to the organic unity of the common German national spirit.

The intellectual debates between the Germanist and Romanist wings of legal scholars encouraged, on one hand, considerable investment in historical scholarship – especially in Classical texts. On the other hand, the application of linguistic study to their own cultures and peoples secured description of the object *Geist* in the present, and was the first iteration of anthropology, sociology, and ethnology as recognizable within modern disciplines.

The Decline of *Geist* and the Rise of *Geisteswissenschaft*

In large part due to the arrogance and totalization of Hegel and his followers, several anti-idealist reactions set in within German philosophical thought after 1830. Empiricism, positivism, and materialism – for example, in Ernst Haeckel's Darwinian evolutionism – replaced the metaphysics of *Geist* with that of concrete reality verifiable through scientific procedures. Politically, the Left Hegelians, including Marx and Engels, demanded the flipping of idealism upon its head, so that culture became interpreted as the product of economic and material interests rooted in class conflict. Similarly, in legal science, rejection of the perceived conservatism of Savigny and his followers contributed to a returned interest in codification and positive theories of law as outlined by Rudolf Ihering. This utilitarian analysis of law and the product of will and conflict led directly to the next phase of legal science and political economy, in which Ferdinand Tönnies, Max Weber, and Werner Sombart were inculcated.

Prominently, the German historical school of economics surrounding Gustav Schmoller, Lujo Brentano, and others rejected the abstraction of both the classical English political economy – Manchesterismus and Hegelian idealism. Focusing instead on empirical material, especially statistics and monographic surveys of urban conditions, the German historical school further extended the trend toward objective study of contemporary society. At the same time, historical interest in Prussian bureaucracy resulted in the *Acta Borussica* in 1887 – a team research project led by Schmoller and Otto Hinze. Thus, both the historicist particularism of the jurisprudential tradition were maintained, while the efforts away from grand, abstract theorizing brought researchers 'closer to the ground,' where they could address issues of social reform according to local circumstances.

This was a period of frequent visitation from American scholars, who would become the founders of many of the early social science departments in America, including John W. Burgess, Albion Small, Edward Ross, and others. The influence of both historical legal studies and historical economics cannot be underestimated. The German scholars' principles of empiricism and social reform found their way into historical institutionalist economics, sociology, and political science.

Meanwhile, within Germany, Wilhelm Dilthey struggled to rehabilitate and revise the science of Mind, which he called *Geisteswissenschaft* (Ermath, 1978). Unlike Hegel, Dilthey did not posit an Absolute teleological entity operating through the totality of the cosmos. Rather, Dilthey's historicism recognized that the concepts that actors, communities, and discourses use are constantly shifting and evolving, so the context in which action takes place is constantly changing and becoming something new. Like Fichte, Dilthey emphasized the role of self-consciousness in this process. Indeed, the human sciences must be distinguished from the natural sciences precisely because conscious reflection is built into human experience, so that our confrontation with human life is not a confrontation with passive external objects as in natural science. An adequate philosophy of knowledge would engage with the history of knowledge itself. Thus, the primary science should be that of 'Mind' – hence, the priority of *Geisteswissenschaft*, or humanities, as the basis for a science of science.

Dilthey's conception of psychology differed from the materialist and empiricist variants developing concurrently through the experimental work of Gustav Fechner, Hermann von Helmholz, and Wilhelm Wundt. In this sense, his work stands in closer relation to Friedrich Schleiermacher's social psychology, as well as the *Lebensphilosophie* (life philosophy) of Henri Bergson, Friedrich Nietzsche, Edmund Husserl, and, later, Martin Heidegger. Dilthey insisted that the object of human scientific study is 'life' – the processual energy flowing through the concrete course of conscious experience. Though constantly changing, life contains relatively stable coherence and structure which can be analyzed and studied scientifically.

Spirit's Tail: The Lost Legacy of the Concept of *Geist*

Despite Dilthey's best efforts and initial success in carving a space for *Geisteswissenschaft*, developments in Germany and elsewhere during the course of the twentieth century led to changes in the human sciences that relegated the concept of *Geist* to the dustbin of history. Most significant in this decline was the political use of the term *Volksgeist* during the Nazi era. Drawing on Herder's nationalism, Adolf Hitler developed the ideology of the Third Reich according to a racist image of the Aryan race and the German *Volk*. Ever since, the idea of positively studying an objective national spirit has become suspect within the social sciences.

Well before this nail in the coffin, however, the term was losing its salience, even as the approach engendered by its use was leaving final imprints on the emerging disciplines of sociology, legal realism, psychology, anthropology, and philosophy. During the late nineteenth century, popular mystical movements associated with 'spiritualism' grew in prominence within English-speaking countries especially. Spiritualist groups sought access to transcendental realms via Mediums, tarot, astrology, and other practices since deemed 'pseudoscientific' (Brandon, 1983). Broadly linking with novel European interest in Eastern religions, scientific advances in electromagnetism and totalizing metaphysical philosophies including Theosophy, Anthroposophy, and Occultism, these discourses were typically rejected by academia. This exclusion reflected not only nonconformity with prevailing scientific methods, but also the over-representation of women in these circles (Braude, 2001). Still members of spiritualist societies overlapped with

'public' sociological, nationalist, and political movements, including the social reconstruction efforts of Patrick Geddes in Scotland, women's suffrage movements, and, indeed, Comte's Positivist religion of humanity. In the long run, these associations between 'spirit' and spiritualism only made matters worse, as pre-World War II social philosophies of this kind were lumped together in a general outdated and dangerous 'irrationalism' – quite out of fashion in the postwar positivist mainstream.

Nonetheless, many social scientific disciplines had already been marked by the ideas and agendas of prior scholars' interest in *Geist*. Franz Boas' four-field anthropology, for example, is widely recognized as a foundational paradigm for modern anthropological study. And yet, Boas' nonracial, culturalist, and systematic study has been described by George Stocking (1996) as "*Volksgeist* as Method and Ethic." Just as the legal scholars, historical economists, and *Geisteswissenschaftlicher*, in Germany distinguished the 'historical,' 'positive,' and 'empirical' from the cultural, meaningful, and abstract – so, too, did Boas' separation of cultural anthropology from bioanthropology, archaeology, and linguistics reflect the organic unity of differentiated analytic spheres.

Similarly, the legal realism of Oliver Wendell Holmes, and, indeed, pragmatist philosophy more broadly would have appeared out of an historical vacuum without reference to Hegelian idealist influences (Menand, 2002). To this day, the social sciences struggle to connect the logical contradictions between the dualisms of individual/society, structure/agency, and so forth. In so doing, we follow the contours of problems that earlier scholars of *Geist* often found noncontradictory – precisely because the mediating, relational concept of spirit provided the organic connection between universal and particular. Contemporary terms – e.g., habitus, network relations, reflexivity, etc. – provide substitutes with greater technical precision, but, perhaps, less ethical force; and, certainly with less of the 'spirit' of the previous Age at the roots of our disciplinary history.

The 'Spirit of Capitalism' in the German *Geist*

We can thus return to the discussion of Weber's classic study of the 'spirit' of capitalism. Some scholars have rightly drawn attention to Weber's training in the historical jurisprudential tradition of Wolfgang Mommsen, and the homology between his categorical scheme and that of Rudolph Ihering (Turner and Factor, 1994). Others have noted the influence of the 'younger' German historical school of Schmoller et al. (Shionoya, 2006). Certainly, Weber was extending these traditions into new territory, and in so doing, he helped differentiate sociology from these older traditions.

In its most specific context, Weber's work was an extension of Werner Sombart's own description of capitalism as an 'objectified *Geist*' embodied in new forms of organizations and technology. Sombart's cultural source for this spirit of acquisitiveness, competition, and rationality came from the bourgeois mentality emerging from the Renaissance. Weber's contribution repositioned the same spirit, within the paradoxical source of ascetic Protestant sects. Without diminishing Weber's achievement, he was not necessarily the 'father' of all that he is given credit for in contemporary social science. The notion of 'objected Spirit,' the notion of *Weltanschauung*, and the *Verstehen* approach were recognizable in Dilthey's *Geisteswissenschaft* program, and Weber's 'ideal-typical' approach was only a few generational iterations removed from the early post-Kantian idealists, Hegal and Herder.

In recalling the admittedly archaic terminology in his foundational essay, Weber recovered the utility of addressing an object which was familiar to contemporary German scholars. Though positive usage had lapsed by 1905, the term *Geist* nonetheless retained a technical terminological thrust even in his own time. Though this 'object' has since been equated with culture, or religion, or rationalization depending on one's interpretation of the Protestant Ethic thesis, we are wise to position Weber's innovative analysis within the ideational context in which it historically emerged. Indeed, in so doing, we recover the original historicist spirit of these scholars' foundational contributions to the human sciences.

Abstract

Ernest Gellner's prolific writings were anchored in his early philosophical studies in Oxford, notably of Hume and Kant. As a social scientist he drew on Weber, Durkheim, and Malinowski, rejecting both the economic determinism of Marxism and all relativist, idealist currents. His models of nationalism, Islam, and civil society have been much debated, and he exercises a diffuse influence in historical sociology and social anthropology. Gellner's social philosophy of modernity has affinities to that of Popper and Hayek, but he is distinctive because he couples his insistence on the cognitive superiority of Western rationalist individualism with a deep appreciation of the diversity of human communities.

Introduction and Life

Ernest Gellner was a self-proclaimed 'Enlightenment fundamentalist' with a unique grasp of the world in which he lived. He ignored boundaries between philosophy and several branches of social science, working against the grain of his generation in all of them simultaneously. Though he spent almost all his adult life in Britain, where he became an influential public intellectual (to the limited extent that Britain is able to host this species), he was also a Central European and a much-traveled multilingual cosmopolitan. Gellner was born in Paris on 9 December 1925 and spent his childhood in multiethnic Prague. His family moved in perilous conditions to England in 1939 following the Nazi invasion; some close relatives did not survive the Holocaust. The significance of these events and of his Jewish middle class background for his work has been carefully explored by his biographer (Hall, 2010). At Oxford University, where his studies were interrupted by military service in the Czech Brigade, Gellner concentrated on. After teaching this subject for 2 years at the University of Edinburgh, he joined the Department of Sociology at the London School of Economics (LSE) in 1949. Here he concluded that British academia had little to say about what really mattered in the postwar world. However, positive stimulus came from his discovery of the cohesive intellectual community of social anthropologists in the department established by Bronislaw Malinowski. Gellner established his reputation with *Words and Things* (1959) a withering critique of the linguistic philosophy that was dominant in Oxford. In 1962, he was awarded a doctorate in social anthropology, based on fieldwork in Morocco which he had pursued alongside mountaineering expeditions in the High Atlas. *Thought and Change* (1964) was a vigorous declaration of intent toward the social sciences, anticipating many of the themes that he followed up in later years, including his celebrated theory of nationalism. After two more highly productive decades at the LSE, in 1984 Gellner was appointed to succeed Jack Goody as William Wyse Professor of Social Anthropology at Cambridge, where he was also elected to a Fellowship at King's College. After retiring, from 1991 he spent much of his time in Prague directing the Center for the Study of Nationalism at the newly established Central European University. He died in Prague on 5 November 1995.

Philosophy, Anthropology, and World History

Gellner's interests extended well beyond the conventional boundaries of the subjects in which he held academic posts. His prolific writing was always anchored in his early philosophical studies, particularly in Hume and Kant, augmented later by his readings of Weber, Durkheim, and Malinowski. In short, Gellner drew on classical sources in several disciplines. Negative influences were equally important. Marxism was always rejected, ostensibly because of its extreme economic determinism, though his encounters with Soviet power in Prague shortly before he left the city for good in 1945 must also have influenced his position. Much of Gellner's own work emphasized a materialist standpoint and he later cultivated an enthusiastic curiosity toward Soviet Marxist anthropology (Gellner, 1988a; Skalnik, in Malešević and Haugaard, 2007). He was even more emphatic in his rejection of what he termed the relativism of the later Wittgenstein, and of the postmodern trends that became prominent across the humanities and social sciences in the last decade of his life. For Gellner, the truths which mattered were independent of 'culture.'

Some critics attacked Gellner with the old bogey of positivism, and some of his more polemical formulations do indeed expose him to such charges. However, in the fuller statements of his philosophical position (Gellner, 1975, 1985) he shows that the central epistemological problems that confront the social scientist are indeed necessarily different from those of the natural sciences. Gellner's distinctive 'metaphysic' (Hall, in Malešević and Haugaard, 2007) is a reconciliation of the scientific with the humanistic, with the ultimate goals of 'legitimating belief' and resolving the puzzles of world history, notably the emergence of 'modernity.' Our modern condition, he argues, requires the rejection of all comforting ideologies in favor of an austere 'bloodless universalism.' At the end of his most concentrated engagement with the work of Karl Popper, from whom he drew much inspiration while maintaining a critical distance, he concluded that "… the positivists are right. For Hegelian reasons" (1985: p. 67).

Gellner's combination of philosophy with anthropology had nothing in common with the continental genre of philosophical anthropology. It was more like a new form of *Universalgeschichte*. Together with the philosopher Ian Jarvie, he

hailed Bronislaw Malinowski as the founder of a social science that offered a better handle on the real world than idealist philosophers in Oxford or evolutionist sociologists at the LSE. When Gellner realized much later that Malinowski had obtained his doctorate in 1908 with a study of Ernst Mach's *Empiriokritizismus*, it was clear to him that in making long-term fieldwork among flesh and blood individual actors the revolutionary basis of anthropological knowledge, Malinowski had simply reverted to the ultra-positivism he had imbibed in his youth. Gellner's fascination with Malinowski led him, late in his career, to further explorations of the founder's intellectual roots in late Habsburg Cracow and to an illuminating (posthumously published) contrast with another product of the same imperial milieu, Ludwig Wittgenstein, whose path was so different (Gellner, 1998). Gellner was greatly attracted by the Pole's combination of cultural nationalism with political internationalism. He was somewhat dismayed to realize that Malinowski himself, alongside all the hard facts he collected on the Trobriand Islands, had made far-reaching concessions to the power of magical words (and thus to linguistic philosophy, the specter of which never ceased to haunt Gellner).

The synchronic character of Malinowski's functionalism was rationalized by Gellner as the natural aversion of a Pole to the Goddess Clio, who had treated his own nation so unkindly. By breaking with the speculative evolutionism of James Frazer and Edward Tylor, twentieth century ethnography, as pioneered by Malinowski, had set new scientific standards. Nevertheless Gellner always argued for reopening the older conversations about diachronic development. From this point of view, he engaged in debates with hunter-gatherer specialists such as his LSE colleague James Woodburn, prehistorians such as Paul Mellars in Cambridge, and numerous Soviet colleagues whose anthropological paradigm had never confined them to the synchronic. Scholars such as Anatoly Khazanov (for pastoral nomads) and Viktor Kabo (for hunter-gatherers) could not match Malinowski when it came to analyses of micro-level, short-term social dynamics, but their long-term visions were equally important for Gellner's grasp of social anthropology as both contemporary social science and world history.

Malinowski's functionalist holism was not the only component of British social anthropology which appealed to Gellner. A.R. Radcliffe-Brown's insistence on the comparison of social structures was still very influential in the 1950s. Gellner implemented this in own ethnographic work, which prioritized pattern and system, rather than close-up analysis of the flux of events (Gellner, 1969). He also took something of the spirit of Radcliffe-Brown's 'natural science of society' agenda with him when he turned to history. This culminated in a three stage philosophy of history, the fruit of his decades of study in various anthropological traditions and in historical sociology (Gellner, 1988b). His aim was to explain long-term evolutionary changes both in terms of the distribution of economic and political power and in terms of ideas and ideologies. Gellner developed these themes most productively in a famous seminar at the LSE which he led jointly with Michael Mann and John A. Hall. His manner of explicating entire eras and societies (or cultures, or civilizations) by means of elegant structural models or ideal types was very much at odds with most of his anthropological contemporaries, who stressed the importance of local knowledge and hermeneutic interpretation. More controversially, Gellner insisted, with increasing vehemence as time went by, that *one* culture, namely that of the West, based ultimately upon premises of science, Cartesian rationality, and individualism, was technologically and 'cognitively' more powerful than all others. To pretend otherwise, in the manner of the relativist philosophers and their admirers in anthropology who insisted that other knowledge claims were equally valid, was romantic nonsense. The challenge was how to explain the dominant power of the West and how best to spread the benefits of that superiority in our modern world.

For many critics, of course, this is an unacceptably Western way to pose the question. For example, Jack Goody, Gellner's predecessor in Cambridge, argues for the distinctiveness of Eurasia, not Europe, and is skeptical of theories proclaiming just one recent breakthrough to a condition called modernity. In Goody's view, China and Europe alternated at the forefront of science and technology from the late Bronze Age onward. By contrast, Gellner agreed with sociologist John Hall and historian Patricia Crone in emphasizing the uniqueness of Europe (he was also stimulated by the work of historical anthropologist Alan Macfarlane, his closest intellectual ally in Cambridge, but judged that this colleague went much too far in stressing the peculiarities of the English). His arguments tend to be as Eurocentric as those of Weber himself. Hall (2010) points out that Gellner attaches no self-congratulatory moral significance to the 'European miracle'; but it is often unclear in his work as to what exactly he means by this term (and similar images such as the 'great escape'). In economic history it is usually taken to refer to the transition from *Agraria* to *Industria*, the causes of which must be sought in new forms of polity and production. But for Ernest Gellner the key variable sometimes seems to be not so much industrialism but a vaguely specified novel mode of cognition. His biographer covers over this tension in his work by opting for the broader blanket term 'modernity.'

Nationalism and Modernity

There can be little doubt that, at least since the publication in 1983 of *Nations and Nationalism*, Ernest Gellner is best known for his work on nationalism. It is important to place this component of his work in the wider context of his interests throughout his career, and to recognize its genesis and early formulation in *Thought and Change* (1964). Nationalism was a driving force in the anticolonial movement in Morocco to which Gellner was a witness. More importantly, it was also the force which had broken up the multicultural empires of Eastern Europe and caused the catastrophes that had clouded his family history. The benign, emancipatory potential of nationalism was evident in the successful nation-states of Britain and France, but how could such models be emulated in what scholars were beginning to term 'the Third World'? This was the era of modernization theory, led of course by the United States, the dominant global power. The fragmentary archival sources that we have for these years show that Gellner, too, shared a widespread postwar optimism that the deployment

of new technologies could eliminate hunger, poverty, and 'nastiness' from the human condition once and for all. Much later, in a remarkable letter to Perry Anderson in 1981, he professed to being a principled Philistine, ready to accept a dumbing-down of European high culture in the interests of social progress ("… I am prepared to pay the price of vulgarity for peace, reasonable diffused prosperity and equality" – cited in Hall, 2010: pp. 159–60).

According to Gellner, the most basic condition for this modernist utopia was a new form of polity, one in which the boundaries of the state would correspond to those of the culture. Whereas his LSE colleague Elie Kedourie had emphasized the dissemination of the nationalist *idea* from its origins in Europe, Gellner stresses the uneven spread of industrialism and the functional needs of an industrial society, which requires a highly mobile labor force and educational institutions that promote literacy in a single 'high culture.' The individual human being emerges from such training as a 'modular man,' capable of performing many tasks in the course of his career (Gellner was notoriously insensitive in his work to the dimension of gender). Consequently, the whole society was characterized by high levels of both occupational and social mobility. This society was radically egalitarian in comparison with the agrarian empires of earlier centuries. This model, elaborated in several variations over more than three decades, was supported not with fieldwork materials but with vivid suggestive sketches, notably that of 'Ruritania' (1983), to indicate the combination of economic, political and emotional factors that could lead the elites of peripheral cultural groups to mobilize the masses to pursue an independent state. The Ruritanian allegory was evidently colored by his Central European roots, and Gellner may also have been influenced by earlier scholars with a background resembling his own, such as Hans Kohn and Karl Deutsch. In his later works (Gellner, 1994, 1996), he elaborated four 'time zones' for the development of nationalism, moving eastward across Europe from the Atlantic seaboard.

Gellner's model was an elegant general theory which, with its stress on structural principles, neatly complemented Benedict Anderson's emphasis upon 'imagined communities,' in a well-known study published almost simultaneously with Gellner's definitive statement (Anderson, 1983). Gellner felt that Anderson's emphasis upon the new technologies of print capitalism failed to acknowledge the enormity of the transformation from agrarian empire to industrial nation-state. "It must be repeated that nationalism is a phenomenon of *Gesellschaft* using the idiom of *Gemeinschaft*: a mobile anonymous society simulating a closed cosy community" (Gellner, 1996: p. 74).

The Gellnerian model has attracted both admiration and criticism (Hall, 1998, 2010: Chapter 10). Some of the problems are those inherent to functionalist theories generally, though these have their defenders (see Mouzelis in Hall, 1998; in Malešević and Haugaard, 2007). Empirically, the Gellnerian model is not so easy to operationalise. Historians and above all historical sociologist Anthony Smith have pointed out that many, if not most modern nations demonstrate more complex continuities with the ethnic groups of the agrarian age than Gellner's model allows. His account of nationalism's geography is equally problematic. Even within Central Europe, one finds Ruritanias such as Slovakia (which Gellner visited as a Boy Scout in the 1930s, and probably supplied the inspiration for his parable) jostling alongside both newly industrialized regions such as Bohemia and old gentry *nacji* (such as that of Poland, one to which Malinowski was proud to claim allegiance, which had once possessed a state but contrived to lose it). The patterns, where there were any, could hardly be reduced to the uneven spread of industrialism. In short, the model does not work, not even in Bohemia (Hall, 2010: Chapter 10). It offers little help in predicting the circumstances in which national sentiment becomes 'hot,' partly because the emphasis is placed on economic development and there is no adequate engagement with (geo)politics, international relations, the growth of bureaucracy, and warfare; and partly because incalculable human subjectivities are a key element in the model, notably elite consciousness of humiliation and propensities to resist and/or to cross cultural boundaries.

Hall (Hall, 2010: Chapter 10) points to a major 'wobble' in Gellner's views following the collapse of the Soviet Union. He seems at this point to have changed his mind concerning the basic desirability of the nation-state. The structural need for social homogeneity, which had destroyed the cosmopolitan world in which he grew up, suddenly seemed less attractive in the 1990s. Repeated eulogies of Franz Joseph reflect the direction of his thought in these years, even though he remained reluctant in print to defend federations created by socialists. Nor did he engage closely at all with the new 'multicultural mess' (Eriksen, in Malešević and Haugaard, 2007) in the old-established, nation-states. These weaknesses limit the usefulness of Gellner's work on nationalism and cultural diversity, even for the European context which inspired it; but it remains the most fruitful ideal type in the social science study of nationalism.

Islam

When it comes to Islam, Gellner's abstract model was nourished not with childhood memories but with data from many years of fieldwork in the High Atlas mountains of Morocco. His monograph, *Saints of the Atlas* (1969), an analysis of how charismatic religious specialists contribute to the maintenance of political order in the absence of state power, is a classic of the British social anthropological school. Intellectual inspiration was drawn from the segmentary lineage theory of the French tradition (Durkheim, and behind him Masqueray and Fustel de Coulanges) as well as from E.E. Evans-Pritchard in Britain. But it was typical of Gellner that, in expanding upon the significance of his local study, he invoked the cyclical models of tribal–urban interaction developed centuries earlier for the Arab world by Ibn Khaldun, and managed to combine them with the religious sociology of David Hume, notably his concept of 'enthusiasm.' Gellner generalized his composite 'pendulum swing model' to the entire Moslem world (initially in the 1960s and later, greatly elaborated, in Gellner, 1981: Chapter 1). It followed from his schematic view that the strict text-based high culture of Islam made it the most modern of the great religions. It was deeply puritanical. Given Weber's famous thesis of the elective affinity between Calvinism and the 'spirit of capitalism,' it seemed to follow that Islamic

societies would be receptive to the modernizing forces of secularism and nationalism. In later years, the growing strength of 'fundamentalism' in the Islamic world was explained in terms of the availability of this modern puritanical faith as a compensatory resource to populations unfortunately prevented from gaining access to the Western institutions of the nation-state and civil society.

Gellner's penduum-swing model of Muslim societies has not been taken up to the same extent as his model of nationalism. Even in the local Moroccan cases, his application of segmentary theory has been heavily criticized by later fieldworkers (see Munson in Hall and Jarvie, 1996). Whereas Gellner showed flexibility in modifying his theories of nationalism to the end of his life, he defended his ideal type of Islam intransigently. Hall (2010: Chapter 9) joins many previous critics in judging Gellner guilty of 'essentializing' Islam, with models that are 'crude' and even 'a little facile.' His biographer is at the same time respectful of Gellner's extension of the Weberian thesis, seeing it as a vital component of his general theory of modernity. In effect Gellner postulates a more 'generic Protestantism,' one which posits a 'rigid and austere deity [who] had no cognitive favourites,' as a precondition, or at least a significant enabling factor, for the great escape from agrarian society. But if the *ulema* of the Islamic city epitomize the puritan emphasis on texts and direct communication with a jealous God, then why was Islam not at the heart of this breakthrough? Gellner has no answer. His arguments that Islam is well adapted to modernity and thus highly immune to secularization are not borne out in the social realities of contemporary Muslim communities. Yet Gellner was no crude Orientalist: he was certainly respected in Morocco, had numerous distinguished Muslim students, and arguably possessed a deeper, more sympathetic understanding of Muslim communities than the scholars with whom he tried to debate these matters, notably Edward Said and Clifford Geertz.

Socialism and Civil Society

The Marxist–Leninist regimes of twentieth-century Eurasia were another form of social organization – and of faith – that fascinated Gellner. As with nationalism the reasons had much to do with his family history. Although he visited the Soviet Union frequently from the early 1970s and spent a year in Moscow at the height of *Perestroika*, most of his research was textual. As noted above, he was deeply interested in the questions of social evolution addressed by Soviet ethnographers, who continued debates with colleagues in archaeology of a kind that had largely ceased in the West following the Malinowskian revolution. At the same time Gellner delighted in reading between the lines of ethnographers' adaptations of Marxist theories in order to see what light these might throw on Soviet society (1988a). He did not predict the demise of the socialist system. However, his first-hand observations of socialist disenchantment in the 'squalor' of the Brezhnev years confirmed his materialist intuition that no doctrine promising salvation here on this earth was likely to endure if the ideologues could neither satisfy accelerating consumer expectations nor control corruption and widening inequalities.

In his last years, Gellner embraced an ideal of 'civil society' as the alternative to the Marxist-Leninist dystopia. Strong mediating institutions between the state and its citizens were hailed as the necessary basis for a pluralist democracy that would avoid the disasters of socialist central planning and all other forms of totalitarianism. *Conditions of Liberty* (1994) has much in common with Samuel Huntington's contemporaneous *The Clash of Civilizations* (Huntington, 1996). We see here a significant shift in Gellner's values from the early 'philistine' endorsement of postwar development policies. By the 1990s, with the Cold War over, he is content to sacrifice living standards and accept the massive widening of inequalities as the price to be paid for 'liberty.' He stops short of endorsing the 'free market' policies of the neoliberals, but insists that the role of the state must be clearly differentiated from the economy. 'Our' civilization, epitomized by a 'modular man' who opts in and out of free associations within a nationally defined high culture, is contrasted not only with Soviet totalitarianism but also with the 'tyranny of cousins' that Gellner had known in Morocco. Neither 'traditional man' nor Homo Sovieticus have any room for individual self-expression, in the former case due to a 'demanding culture' and in the latter due to the fatal combination of modern technologies with the monist pathology of Marxism, which in Russia was a seamless extension of Byzantine Caesaro-Papism. Only a separation of hierarchies in an open, liberal society can save us, argues Gellner. However, it is still not possible to 'validate' this Western ideal, since that step would imply some new form of absolutized ideocracy, which is disqualified in his definition of modernity. This is Gellner's final position: "We have to live with this" (1994: p. 214).

With this late work, to an even greater extent than in his earlier studies of world history, of nationalism, and of Islam, Gellner laid himself once more open to charges of ethnocentrism, or perhaps more precisely, Eurocentrism. The shrill fetishism of civil society reflects both a harshening of his political stance and a coarsening of his rhetorical skills. Gellner seems to forget the healthy starting point of his critique of the anthropologist-philosophers of the 1950s. He himself had once shown that real flesh and blood individuals enjoyed considerable room to maneuver, despite the seemingly rigid concepts and rituals that structured tribal Morocco. In the course of his career, he had supervised and examined innumerable ethnographic studies documenting the concrete realities of diverse societies all over the globe, including the mediating institutions of Islamic and socialist societies. Yet in the last major book published in his lifetime he forgot all this and argued instead that a specifically Western civil society was the right way to fill the void or 'vacuum' left by Soviet socialism. He paid little attention to what anthropologists and sociologists were already reporting about the high social costs of the shift to new forms of politics and economics throughout the former Soviet bloc. In short, he argued in the manner of a politically conservative linguistic philosopher, rather than a critical, empiricist, social scientist. The slogan 'civil society' supplied the later Gellner with an ultimate ethical grounding, though he had spent most of his

life insisting that no such grounding was possible and a formal 'validation' to support its prescription to the world was even now out of reach.

Impact and Assessment

Testimony to Gellner's influence in his lifetime can be found in a remarkable multidisciplinary collection of critical essays, to which he delivered an eloquent reply shortly before his death (Hall and Jarvie, 1996). One obvious key to his fame lies in the topicality of the subjects he treated: nationalism, Islamic fundamentalism, socialism, and civil society were all vital problems of the age. Another is the appeal of a scholar who was not merely disrespectful of disciplinary barriers but who consistently opposed many of the most influential intellectual currents of the day. His critique of Oxford philosophy was followed by equally irreverent dismissals of many other 'churches,' which space has not allowed me to discuss in this essay: Parisian structuralism, Frankfurt neo-Marxism, psychoanalysis, the 'Orientalism' paradigm of Edward Said, and every variety of postmodernism. Even his relationship with social anthropology, the discipline in which he came closest to finding a home, was uneasy. He remained basically loyal to the canons of Malinowski's functionalism and Radcliffe-Brown's structural-functionalism long after these had been abandoned by the profession, somehow combining these preferences with an even less fashionable sympathy for evolutionist agendas. Gellner's anti-relativism led to countless sharp disagreements in anthropology, for example, with Rodney Needham over the nature of kinship, and with Clifford Geertz, who he recognized as the leading contemporary exponent of the erroneous idealistic concept of culture.

Neither anthropology nor any of the other disciplines to which he contributed, has a Gellnerian school. With the hindsight of two decades his positions in numerous areas seem decidedly old-fashioned: for example, his blindness toward gender issues; toward the ecological consequences of the economic growth which was to overcome 'nastiness' on our planet; and toward multiculturalism in countries such as Britain, with all its implications for his theory of nationalism. And yet his ideal types and allusive fables of modernity have proved endlessly stimulating. Gellner's considerable impact as a public intellectual owes much to his forthright defense and provocative reformulations of universalist enlightenment ideals in a century in which these foundations came to seem increasingly fragile to the great majority of philosophers and social scientists in the West. An iconoclastic temperament and a distinctive aphoristic literary style helped him in communicating his message. This stubborn defender of outmoded ideals of rationality, clarity, and above all truth, delighted in controversy and had a preference for striking images and analogies over footnotes and the more prosaic techniques of social science. An integral part of his appeal to some, his acerbic wit and affectation of anti-intellectual positions only intensified his bogeyman status for others.

Indeed, Gellner was not the most painstaking of scholars – neither in the field nor in the library. He is best seen not as a backward-looking defender of European traditions, but as a thinker who strove to adapt a European liberal heritage to reach a better understanding of the central problems of the world in which he lived. Caricatures such as that of enlightenment fundamentalist are wide of the mark (even if he himself regularly suggested such labels). Despite his criticism of Wittgenstein and of the relativist trend in anthropology, he was no more ready than Malinowski to dispense with the concept of culture. He insists on the uniqueness of modern Western cognition because it really is stronger than any other. He embraces it personally, along with what he takes to be its socio-political corollaries, above all civil society; but even at the end of his life, in the aftermath of the Cold War, when he applies all his rhetorical genius to convince us that liberal individualism is not just cognitively more powerful but also *better*, he concedes that he cannot validate this. Compared to Popper and Hayek, this Central European liberal has a nagging awareness that cohesive human communities require stronger social foundations than those which the modern West has been able to provide.

This lingering doubt, an implicit balancing act frequently disguised by the swagger of his prose, make Gellner's quest a continuing source of inspiration in the new century. He would be the first to applaud new ideal types that upstaged his own: original fables to replace his account of Ruritania in order to capture new empirical realities. Ernest Gellner was himself a remarkable 'modular man' – not of a national community but of twentieth century Western scholarship. In an age of specialization, a scholar who transcends the boundaries is easy to dismiss as a gadfly or a maverick. Gellner made the most of the outsider position thrust upon him by his early life. His work has a high degree of unity and consistency. But there are also significant modifications, 'wobbles,' and subtleties and ambiguities easily missed if one gets lost in his polemical pyrotechnics. Gellner repeatedly trivialized relativist positions as mere 'cultural wallpaper,' but he was not disrespectful of 'difference.' What he objected to was 'excessive charity' toward complex concepts, which led some anthropologists to assert radical alterity and fail to recognize the common sense knowledge of their subjects. He objected to the conceit which placed multifarious other cultures on a par with modern scientific knowledge. The latter had manifestly demonstrated its superiority through the changes it had wrought in the world, a 'brute' fact that stood beyond any ethical justification. This insistence on rational science as the basis of a new mode of 'cognition' leads John Hall to claim that Gellner is 'more Weberian than Weber himself' (2010: p. 229). Indeed, in the fullest outline of his philosophy of history (Gellner, 1988b), the man who had castigated idealist theories in philosophy and in the explanation of nationalism comes close to arguing that our modern world only became possible when we somehow began to *think* more rationally, in the spirit of a 'generic Protestantism.'

Abstract

Recent research on the motivation and achievement patterns of girls and boys has called attention to several significant trends. Notable developments, such as the favoring of girls on many reading-focused assessments and a plethora of new studies on boys, appear both in the United States and internationally. This article covers several prominent gender-related trends in motivation research on both national and international levels. Specifically, the article discusses (1) the increased focus on boys' motivation and achievement, (2) differences in motivation and achievement within gender, (3) cross-national trends in gender-related motivation and achievement patterns, and (4) the expanding of existing theoretical motivation frameworks.

The past decades have brought forth much research on trends related to the motivation and achievement patterns of girls and boys both in the United States and abroad. Most notable in the current literature is the fact that girls have, across academic domains, most countries studied, and cultures, caught up with boys in terms of their performance on school-based and national assessments. In addition, girls are more likely than boys to complete secondary school by either completing standard schooling or earning a high school/secondary school equivalency degree (Meece and Askew, 2012). Regarding postsecondary education, in most Western countries, more women than men graduate college with a bachelor's degree. However, women continue to be less involved in mathematics-intensive fields during and after college in all countries studied (NSF, 2013; Watt, 2008) despite boys' and girls' comparable performance on mathematics assessments (Lindberg et al., 2010). Relatedly, in the USA, women's participation in the social and biosciences has dramatically increased since 1991, but men are still more likely to enter the physical sciences (NSF, 2013). These trends, such as the favoring of girls on a variety of large-scale reading assessments and the largely equivalent performance of girls and boys in the domains of science and mathematics, are apparent across geographic boundaries.

In recent decades, educational researchers have begun to focus on the underlying social and psychological processes and mechanisms driving the remaining gaps in gender-differentiated achievement patterns. Much of this new literature in Western countries centers on an academic choice model, rather than a personality theories of motivation. As such, current work looks at how students make sense of their academic achievement experiences and come to value particular academic and career domains. More recently, the field has shifted again. This time, from utilizing theories strongly rooted in motivation beliefs to theories that include broader socio-cultural influences and their combined effect on motivation (e.g., how teacher characteristics interact with student ethnicity to influence motivation).

Gender-related motivational processes are key to understanding the educational trajectories of boys and girls in countries across the world. The expectancy-value framework enables researchers to model how social-cognitive processes (e.g., within classroom and familial contexts) shape student motivation. Motivation and achievement trends not only inform our understanding of students' beliefs, values, choices, and subsequent educational outcomes, they are also telling of the gender-related educational progress made in the past decades and the needed changes in educational programing moving forward (Watt et al., 2012). This article discusses several gender-related motivation and achievement trends occurring on both national and international levels. The article covers five key topics (1) the increased focus on boys' motivation and achievement, (2) differences in motivation and achievement within gender, (3) cross-national trends in gender-related motivation and achievement patterns, and (4) the expanding of existing theoretical motivation frameworks.

Increased Focus on Male Students in US Studies

For many years a strong concentration on girls' achievement and advancement dominated much of the academic literature on gender and motivation. Research on US students in the 1980s and 1990s focused on gender differences in mathematics and science achievement, particularly in regard to girls' motivation. However, in recent years, an abundance of research on male students has emerged. This surge of research has found several notable trends. For example, in comparison to girls, boys receive lower grades (Cornwell et al., 2013) and take fewer advanced classes (Taylor and Lorimer, 2002). Girls, on the other hand, in the US school system and abroad, have made substantial gains in academic performance and are now on par, if not outperforming, male students in a variety of subjects. Results from the National Assessment of Educational Progress since 2008 and through 2011 show tests of reading and writing favor girls (NCES, 2008; NCES, 2012).

Along with assessment and grade-related trends favoring girls in US studies, research also documents major discrepancies in secondary and postsecondary graduation rates and postsecondary academic pursuits of male and female students. For example, boys currently graduate high school and college at lower rates and do not demonstrate clear aspirations for higher education compared to their female counterparts (Meece and Askew, 2012). There are also clear discrepancies in regard to fields of study during postsecondary education and students'

subsequent occupational choices. Whereas the gap between men and women who choose to pursue the life sciences has significantly narrowed, women are still less likely to choose mathematics-intensive fields of science such as engineering, physics, and many technology-related areas (Ceci and Williams, 2010).

Despite the presence of these pronounced trends, scant research is available to explain modern gender-differentiated patterns in academic motivation, achievement, and post-secondary attainment of US students. Research in the US in the 1980s and 1990s, using an expectancy-value motivation framework, documented clear gender differences in youth's competency and value beliefs, which were shown to affect the achievement striving of girls and boys (Eccles et al., 1983; Wigfield and Eccles, 2000). This framework was utilized by Jacobs et al. (2002) in conducting a longitudinal study of 761 students from 10 Midwestern schools. This study documented significant declines in both girls' and boys' competency beliefs, with declines varying according to domain and gender. Specifically, girls' perceptions of their ability in mathematics were found to decline at a slower rate than boys. When motivational beliefs related to language arts were examined, boys' and girls' perceptions of ability were similar at the beginning of elementary school, but boys' ability beliefs declined more rapidly than girls beginning in the late elementary years. Jacobs et al. (2002) also documented declines in value-related beliefs across the school years for both mathematics and language arts, with boys demonstrating a more rapid decline in language arts than girls. Although patterns of declines in competency and value beliefs may explain gender differences in academic achievement, these linkages were not specifically examined.

In looking at US-based literature on student motivation over the last decades, there are poignant differences in the motivational beliefs and trajectories of boys and girls. Many recent research efforts have focused on the lowered academic motivation of boys in literacy-focused subjects. Longitudinal, national assessments have provided a rich resource for documenting trends in educational achievement and attainment. However, to date, national assessments of educational progress have generally not included measures to examine motivational processes underlying and explaining these gender-differentiated patterns.

Variations within Gender Groups in Studies in the USA

Throughout schooling, some children deal with harmful discriminatory experiences and intense social pressures, which can greatly affect their motivation. These achievement-related inequities are becoming a significant component of US studies of educational achievement and attainment. In fact, as girls and young women in the United States were making important achievement strides in the 1990s, researchers cautioned the need to disaggregate data by ethnicity, family income, geographic location, and other key demographic characteristics, as these variables can significantly influence the educational experiences of different children. However, although research has consistently found that gender differences in students' schooling experiences are moderated by race and ethnicity (Meece and Askew, 2012), researchers have just recently begun to investigate how gender differences in motivation vary by ethnicity, race, or socioeconomic status (Eccles et al., 2006; Meece and Askew, 2012). Studies that have investigated variations within gender have looked at how race, ethnicity, and contextual variables affect motivation.

Extant research has found that gender-related achievement patterns vary across ethnic groups and can oscillate depending on academic domain and student ethnicity. For instance, African-American girls' and boys' scores on mathematics assessments are relatively equal (Lindberg et al., 2010; Vanneman et al., 2009). Yet on assessments of reading and writing, girls score higher across ethnic and cultural groups (Meece and Askew, 2012). In US studies, the group that has shown the greatest increases in their academic achievement is African-American girls. Over the last 30 years, African-American girls have made significant gains in reading and mathematics compared to their male counterparts. Academic gains for white boys and girls, as well as African-American boys, are not as great (Vanneman et al., 2009).

These gender-related achievement patterns found among students belonging to different ethnic groups have led to increased research on the motivational processes underlying these achievement trends. Many studies focused on African-American students have shown gender differences favoring girls in terms of academic expectations, aspirations, and values. Graham et al. (1998) were among the first achievement motivation researchers to look at gender and ethnicity differences in academic valuing in relation to barriers to academic success. In their original work and in subsequent supporting work, using peer nomination procedures, they have found that ethnic minority girls in elementary and middle school were more likely to report valuing average and high academic achievers than their low-achieving peers. In contrast, although the ethnic minority boys preferentially nominated high achievers during the elementary school years, they increased their preference for low-achieving classmates as they progress through school (Graham et al., 1998; Taylor and Graham, 2007). Consistent with this pattern, Wood et al. (2007) have shown that ethnic minority girls report higher expectations for future educational attainment than their male peers.

Recent research on within-group motivation patterns has begun to examine racial socialization influences. For instance, for boys, racial centrality (i.e., the extent to which one's racial background is important to one's self-concept) is associated with lower risk for negative school-related attitudes and poor grades from experiencing classroom discrimination (Chavous et al., 2008). For girls, higher centrality is associated with protection from peer discrimination toward school importance and academic self-concept (Chavous et al., 2008). Other research has highlighted the importance of racial pride in the study of motivation. Butler-Barnes et al. (2012) found a positive relationship between educational utility beliefs (i.e., the perception that education bears utility for future success) and grades among boys with high racial pride.

In summary, current within-group research on ethnicity and motivation has illustrated several key findings; (1) African-American boys are at particular risk for lack of motivation and school failure, (2) positive racial identity and school utility beliefs are critical to the success of both girls and boys and can have buffering effects against discrimination, and (3) racial discrimination can hinder a student's school-related beliefs.

Cross-National Trends

Research on gender-related motivation patterns has generally stemmed from theory and empirical research generated in the United States. There is less information on the role of student motivation in schooling for other countries. Yet recently, research focused on gender-related patterns of student motivation in different parts of the world has surfaced. In comparing the academic attitudes, beliefs, and achievement of students cross-nationally, many researchers use the Trends in International Mathematics and Science Study (TIMSS) and the Program for International Student Assessment (PISA). TIMSS focuses on assessing learned items from curricular resources and PISA examines mathematics literacy, or the ability for students to apply and engage with mathematics. Several notable trends have emerged from this new focus on cross-national trends.

Trends found in the US regarding gender, achievement, and motivation are present around the globe. This article covers several of these trends, broken into the following four main themes: (1) the advantage of girls on literacy-focused assessments, grades, and college graduation rates, (2) gender-related differences in motivational processes, (3) differences in gender-related motivation and achievement patterns between developing and industrialized countries, and (4) the effects of gender-related stereotyping on achievement.

First, girls do better than boys on literacy-focused assessments, school marks, and rates of graduating from college in many countries around. Indeed, studies using the Organization for Economic Co-operation and Development's Program for International Student Assessment (OECD-PISA) have found that girls receive better grades, graduate high school at larger rates, and garner higher reading achievement scores in most countries (OECD, 2011). Even in countries lauded for their rigorous and exemplary school systems, such as Singapore, there are gender differences in scores on reading and writing assessments. For example, scores on the 2006 Progress in International Reading Literacy Study favored Singaporean girls (Mullis et al., 2007). Using PISA data with a sample of 193 841 fifteen-year-olds, Chiu and Chow (2010) found that girls outscored boys in 95% of the 41 countries included in the sample. This pattern was especially pronounced in Denmark, Norway, Portugal, Sweden, and Thailand (Chiu and Chow, 2010). In other domains, such as mathematics, boys are generally favored, although gender gaps are quite small (less than 5%) in countries such as Finland, Slovenia, Sweden, Indonesia, and Russia. There are no significant differences in performance in science (OECD, 2011).

Current gender-related cross-cultural trends in achievement reflect patterns in student motivation (e.g., beliefs and attitudes). In fact, PISA data at the aggregate level support the conclusion that gender differences in educational choices are more related to students' attitudes and interest in a particular subject than students' actual ability (OECD, 2011). This has led researchers to adopt the belief that many of the trends in secondary and postsecondary education are partially, if not largely, attributable to gendered beliefs and stereotyping, rather than ability (OECD, 2011).

Indeed, research stemming from around the world shows marked differences in boys' and girls' motivation and school engagement. For instance, in Australia, using the Student Motivation Scale, Martin (2004) found that girls were significantly higher than boys in planning, study management, learning focus, and persistence, whereas boys were higher than girls in their use of self-handicapping strategies. Similarly, Lam et al. (2012) examined gender, student engagement, and academic performance among students in Austria, Canada, China, Cyprus, Estonia, Greece, Malta, Portugal, Romania, South Korea, the United Kingdom, and the United States and found that girls maintained higher levels of school engagement and that student engagement explained the gender-related variance in academic performance (Lam et al., 2012). Similarly, research on achievement expectations in several different countries has found that boys rate their math abilities higher than girls. In fact, using TIMSS and PISA data from 69 countries, Else-Quest et al. (2010) found that boys report more positive mathematics-related attitudes and affect girls despite the overall similarities in mathematics achievement between boys and girls.

When gender-related trends in achievement and motivation are investigated in developing countries in contrast to industrialized countries, different patterns arise. In developing countries, girls have poorer educational attainments, particularly as students reach higher levels of schooling (OECD, 2011). Yet, although girls in developing countries have lower educational attainment and are less likely to be enrolled in school compared to boys, girls who have attended school at one point in time make equal or better schooling progress than boys throughout many regions and across age groups (Grant and Behrman, 2010). In addition, current research in developing countries is rife with examples of rampant gender biases in certain societies. Lower rates of social promotion, limited access to educational opportunities, and unequal treatment in society are issues that many girls and women face and are prime areas where continued support and research are needed.

Expanding of Theoretical Frameworks

It is quite apparent from the literature on children and schooling that students do not develop in a vacuum; they exist in a multilayered, complex social world. As such, students and their academic motivation should be studied with these complex social and environmental processes and contexts (e.g., peer processes, economic and political climates, cultural practices) in mind. Fortunately, the past decade has seen a rise in research that includes contextual variables as researchers are beginning to acknowledge the importance of these influences on student motivation. In fact, Perry et al. (2006) assert, "contextual understandings are more integral to research on motivation today, reflecting the general shift in educational research toward situated and social perspectives on learning" (p. 328). The Eccles et al. (1983) developmental model of achievement motivation is one framework that has continuously extended to study combinations of contextual variables (e.g., the effect of both teacher and ethnic influences) affecting motivation.

Since its introduction, the model proposed by Eccles et al. (1983) has examined the role of children's socialization experiences in creating and reinforcing gender-related differences in motivation and achievement. The strong socialization

component of this model examines processes by which socializers (particularly parents and teachers) (1) model sex-typed behaviors, (2) impart different expectations and goals for boys and girls, and (3) support boys and girls when they undertake different activities and skills. This model has continued to yield a rich body of research on children's socialization experiences at home and school (Wigfield et al., 2006).

Indeed, many researchers have applied the Eccles et al. (1983) model to studying how a child's home environment (e.g., interactions with his or her parents and siblings) affects their academic motivation. These familial socialization patterns and relationships are especially key in understanding gendered patterns of academic motivation, as early gendered beliefs are most often formed through interactions with parents. Research has found that gendered beliefs formed in early childhood influence long-term thinking about competency, school valuing, and the self (Meece et al., 2006). Parental beliefs about school valuing and educational aspirations and goals, and even different academic domains, are communicated to children through choice of leisure activities and everyday conversation (e.g., parents talking about their own skills and attitudes) (Eccles et al., 1983). In fact, research shows that parental beliefs about their children's gender and abilities are strong predictors of their children's own beliefs about ability and performance (Bleeker and Jacobs, 2004). Jacobs (1991) found that parents holding stereotypical beliefs regarding males' supposed expert mathematical abilities exhibited less confidence in their child's mathematics ability if they had daughters compared to sons.

In addition to factors in the home environment, school-related influences on an individuals' achievement motivation are critical to study, yet extremely complex. Students come to school with preconceived ideas and attitudes about gender-typed behaviors, and subsequently school often serves as a place where students fine-tune and verify their own beliefs. At school, students see older male and female teachers, staff, and administrators carry out specific roles. For example, women are more likely to take care of young children while men are more likely to appear in management roles within the school (Meece and Askew, 2012). The learning materials, such as textbooks, videos, and computer software, utilized in schools present images of gender-typed behaviors and actions. It is also important to consider the fact that schools significantly differ in terms of geographic location, access to resources, teacher quality, and socioeconomic statuses of families. These factors greatly influence the bidirectional relationship that the child and school experience, which result in varying academic motivational trajectories for individual students.

Recent studies have used the Eccles et al. (1983) framework to examine the complex interplay of African-American youth and their schooling experiences. In one study, Eccles et al. (2006) reported that daily racial discrimination during seventh and eighth grades predicted declines in grades, academic ability self-concepts, and academic task values. However, a strong connection to one's ethnic group acted as a buffer in assuaging some of the negative effects of racial discrimination. In another study, Graham et al. (1998) examined gender differences in the ways African-American youth respond to racial discrimination. Specifically African-American boys, when compared to girls, demonstrated a higher likelihood of devaluing academic success under conditions of racial discrimination. This strategy, they found, enabled boys to maintain positive self-perceptions of ability. African-American girls, on the other hand, placed more emphasis on relationships and approval from peers and teachers, when self-concepts are threatened by racial discrimination. Differences in the ways African-American boys and girls respond to racial discrimination in school setting may explain variations in achievement for this subgroup of US students.

A related line of research is examining the role of cultural stereotypes in explaining gender-related achievement patterns across countries. That is, variations in gender-related cultural attitudes and the valuing of education can trickle down to the student level and greatly influence student motivation. Recent research on the effect of how cultural stereotypes affect student motivation and achievement provides several interesting insights. In particular, using samples of students from around the world (Chiu and Chow, 2010; Nosek et al., 2009), numerous studies document the relation of cultural stereotypes to students' educational behaviors, choices, and performance. For example, Nosek et al. (2009) used a gender-science Implicit Association Test (i.e., a measure of associations between mental representations) with over half a million participants belonging to 34 countries. The researchers found a significant relationship between gender-science stereotyping and sex differences in mathematics and science achievement (Nosek et al., 2009). More specifically, the level of implicit stereotyping in a country was related to the level of inequality in science and mathematics achievement in that country. These findings surrounding implicit stereotypes and achievement patterns may be extended to show disparities in larger participation trends in science and mathematics (Nosek et al., 2009). Related to implicit beliefs and stereotypes, other studies have highlighted the influence of cultural stereotypes on achievement in particular domains (Chiu and Chow, 2010; Fredericks and Eccles, 2002). Chiu and Chow (2010) found that cultural values were linked to reading motivation and achievement. Girls who lived in countries that valued strict gender roles learned less than in other countries.

In summary, recent studies using both social-cognitive and sociocultural frameworks continue to broaden the knowledge base on gender and motivation. These studies highlight the critical role of socialization processes and mechanisms in the home, family, and cultural contexts. There is an abundance of research on these socialization patterns and current research findings are promising for understanding gender differences across and within cultures. Most of this research has been done in the USA. More work is needed in all other countries.

Conclusion

This article examined research focused on several national and cross-national trends regarding gender differences in motivation and achievement. The article focused on four major areas including (1) the increased focus on boys' motivation and achievement, (2) differences in motivation and achievement within gender, (3) cross-national trends in gender-related motivation and achievement patterns, and (4) the expanding of existing theoretical motivation frameworks.

It is clear from international data on student achievement that girls and boys perform equally well in mathematics and science and girls largely outperform boys on reading assessments. However, despite the relative parity of girls and boys in terms of performance, their motivational processes look quite different and may fuel persistent inequalities and gender gaps in participation in various domains. For example, the USA science and engineering workforce is still largely composed of white, male workers (NSF, 2013).

Not only is this kind of gender imbalance in mathematics (and literacy-related) participation present in the USA, it also appears in international contexts (Watt, 2008). Given the finding that motivational beliefs are predictive of certain forms of successful schooling (e.g., high school mathematics participation), it is critical to continue studying domain-specific motivational processes and mechanisms across a wide range of groups to help understand and address continued disparities (OECD, 2011; Watt, 2008; Watt et al., 2012). To help address these critical areas of study, motivation frameworks have recently broadened to examine motivation *in situ* moving from studying student perceptions to investigating interactions and activities (Perry et al., 2006). These new studies largely emanate from social-cognitive and sociocultural perspectives of motivation and marry such variables as family, teacher, and student characteristics, learning and engagement, and instructional tasks and academic domains. In order to promote greater equity in schools and in the workplace, continued research and support targeted at understanding the aforementioned gender-related motivation and achievement patterns is essential.

Abstract

Recent international emphasis has been placed on closing persistent gender gaps in education. In this article we explore current gender gaps in educational outcomes, focusing on students' experiences in developed countries. We then investigate potential causes of the gender gaps, focusing on differences in cognitive and socioemotional skills, socialization, gender stereotypes, and interest. Next, we discuss societal responses to the gender gaps, including movements focused on girls being shortchanged, boys being in crisis, gender differentiated and segregated learning approaches, and attempts to ameliorate gender gaps by reducing the focus on gender. Finally, we end with suggestions for future work.

Introduction

In 2000, the United Nations Educational, Scientific and Cultural Organization (UNESCO), as part of the Dakar Framework for Action, made the goal of "eliminating gender disparities in primary and secondary education by 2005, and achieving gender equality in education by 2015, with a focus on ensuring girls' full and equal access to and achievement in basic education of good quality" (UNESCO, 2012: p. 8). By many measures, significant progress has been made toward these goals. However, even in developed countries, discrepancies persist in terms of test scores and grades in some domains, attitudes and behavior in classrooms, and aspirations for educational and occupational attainment. In this article, we explore these gender differences in educational outcomes. We then investigate some of the proposed causes for these gender gaps and investigate societal responses to the persisting gaps. The article then ends with ideas about future research. Given our experiences and expertise, we focus on data related to children's, adolescents,' and college students' experiences in developed countries. For a more complete discussion of the current state of gender differences in educational outcomes in developing countries, see UNESCO (2012).

Gender Differences in Educational Outcomes

The following sections present recent data on the state of gender differences within education, focusing on test scores and grades, engagement and behaviors in classrooms, and educational attainment.

Test Scores and Grades

Historically, there have been persistent gender gaps in academic achievement. Males have generally outperformed females in mathematics, while females have generally outperformed males in literacy. Current statistics suggest that some of these patterns are slowly changing.

On many mathematics examinations, males slightly outperform females (e.g., Lee et al., 2007; Planty et al., 2009). However, this gap is not consistent across ages and contexts. The gender gap in mathematics performance often does not appear until early adolescence and only in some exams (Ceci et al., 2009). Examining scores on state-standardized exams of children in second- through eleventh-grade US public schools, Hyde et al. (2008) reported no mean level differences between boys' and girls' math performances. Looking at the mathematics exam scores by state and grade level, boys outperformed girls in 21 cases, girls outperformed boys in 36 cases, and there was absolutely no gender difference in nine cases. Looking across countries, in the 2009 Programme for International Student Assessment (PISA), a standardized test that 15-year-old students around the world completed, boys outperformed girls on the mathematics exam by an average of 12 points (or 0.12 of a standard deviation; OECD, 2010). There were, however, variations across countries and economies; while in 35 countries boys outperformed girls, in 25 countries there were no significant gender differences, and in five countries girls outperformed boys.

In comparison to the shrinking mathematics achievement gap, the gender gap favoring females on assessments of literacy are often present from the moment children enter formal schooling and persist across the life course (e.g., Perie et al., 2005; Rathbun and West, 2004; Robinson and Lubienski, 2011). For example, research examining literacy skills in a nationally representative sample of kindergartners in the US has shown that girls not only enter kindergarten with greater literacy skills than boys, but they also learn slightly more across the kindergarten year (Ready et al., 2005). In the 2009 PISA reading literacy exam, in every one of the 60 participating countries and economies, 15-year-old females significantly outperformed their male peers (OECD, 2010). Furthermore, the size of the literacy gap was over three times larger than the math gap favoring males.

Considering children's academic performance in the classroom as opposed to performance on standardized exams, girls have consistently outperformed boys throughout much of the developed world since at least the mid-1900s (Mickelson, 1989). Girls tend to earn higher grades than boys from the time they enter school through the end of college – even in traditionally-masculine subjects like science and math – and these differences are seen across cultures (Perkins et al., 2004). Italian female college students earned higher grades than the males in 11 of the 15 subjects (with males outperforming

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92151-2

females in only one area and no significant difference in three other areas; Castagnetti and Rosti, 2010).

Engagement and Behavior in Classrooms

From the moment they enter school, gaps appear between boys' and girls' behavior in the classroom. Research conducted in the United States suggests that in kindergarten, twice as many boys than girls struggle to pay attention (Zill and West, 2001), and throughout childhood and adolescence, boys consistently engage in more disruptive classroom behaviors than girls (Schaefer, 2004). Further, girls are often rated to be more dutiful and cooperative in classes than boys (Mickelson, 1989). Given these gender differences, it is not surprising that starting in prekindergarten and continuing throughout their educational careers, boys are about four times more likely than girls to be referred to school administrators, suspended, or expelled (Gilliam, 2005).

In addition to behaving more poorly in the classroom, boys also tend to have more negative attitudes about school and teachers than girls throughout their educational careers. In a recent study of US students of 8–18 years of age, Sullivan et al. (2008) found small but consistent differences suggesting boys have stronger negative attitudes about school than girls. In a similar vein, as early as kindergarten, gender differences appear in attitudes toward teachers; for example, boys are more likely than girls to think that their teachers do not like or care about them (Valeski and Stipek, 2001).

Unfortunately, boys' tendency to behave worse in classrooms and endorse more negative attitudes about school and teachers than girls may be related to their lower achievement levels. Inattentive and disruptive classroom behaviors predict poorer academic achievement (Finn et al., 1995). Similarly, negative attitudes toward school and teachers are associated with lower achievement and lower expectations of future success (Baker, 1999; Brier, 1995). Additionally, negative achievement leads students to have more negative attitudes about school, producing a cyclical effect (Valeski and Stipek, 2001). Slight gender differences in classroom behavior and attitudes toward school and teachers at the beginning of formal schooling may, over time, result in large gender gaps in achievement.

Educational Attainment

Historically, females have had less access to education than their male counterparts. Although gender parity persists in most countries in South and West Asia and sub-Saharan Africa, gender parity has been achieved in much of the rest of the world (UNESCO, 2012). In fact, in many developed countries, the persistent gender gaps favoring boys have flipped. In the US, for example, boys are more likely than girls to drop out of school (Bowlby, 2005). Girls, meanwhile, are now more likely than boys to complete high school (Horn et al., 2002), enroll in college (NSF, 2009), and graduate from college (Freeman, 2005). These trends stand in stark contrast to the data from just 50 years ago: in 1960 there were 1.6 males graduating from 4-year US colleges for each female; in 2003, in comparison, there were 1.35 females graduates for each male (Goldin et al., 2006). Other countries have experienced similar shifts – in East Asia and the Pacific, Latin America and the Caribbean, and North America and Western Europe, women went from being the minority of college students in 1970 to the majority of college students in 2009 (UNESCO, 2012). Notably, this flip in the gender gap in educational achievement in developed countries is not due to fewer men participating than in the past; instead, it is due to a dramatic increase in the percentage of women participating in postsecondary education.

Unfortunately, gender gaps in educational attainment are complicated by gender differences in attainment in different educational fields. In 2006, women earned 58% of the bachelor's degrees awarded in the US (NSF, 2009). However, there was considerable variation in the size and direction of the gender gap by field. Women earned 90% of the degrees in psychology and 62% of the degrees in biological sciences. Men, however, earned more of the degrees in mathematics and statistics (55%), physical sciences (58%), and engineering (80%; NSF, 2009).

Potential Explanations for Gender Gaps

Researchers have identified several factors that may play a role in the gender differences that emerge in educational achievement, attitudes, and attainment. In this section, we focus on several broad areas: cognitive and socioemotional skills, socialization, gender stereotypes, and gender-typed interests.

Cognitive and Socioemotional Skills

In the past, scholars argued that gender gaps in educational outcomes could primarily be attributed to differences in overall intelligence. This perspective is not supported by research: today, most experts agree that gender differences in overall intelligence do not exist (Halpern and LaMay, 2000). Indeed, the vast majority of research on gender differences in cognitive skills is consistent with the gender similarities hypothesis (Hyde, 2005): in most areas, males and females are similar.

There are, however, some cognitive differences that may help to explain persistent gender gaps in education. For example, results from a meta-analysis suggest that, on average, males outperform females on visual-spatial tasks starting as early as 3 years of age, suggesting that boys' advantage in this area is not due to differences in life experience alone (Cohen's $d = 0.37$; Robinson et al., 1996; Voyer et al., 1995). These slight differences in visual-spatial tasks may relate to performance on some math and science exams. Females, meanwhile, tend to outperform males in the area of memory, with effect sizes ranging from 0.20 to 0.60. These gender differences, which are consistent across developmental periods and cultural backgrounds, may help explain gender gaps in literacy achievement (see Halpern, 2000 for a review). For example, vocabulary size, which has a strong memory component, is typically larger among females than males. This difference appears as early as 16 months and exists even after controlling for mother–child interactions, suggesting a biological component in girls' advantage in the areas of reading and writing (Huttenlocher et al., 1991).

Gender gaps in self-regulation skills, which have cognitive and socioemotional underpinnings, may also contribute to

gender gaps in education, especially in areas related to classroom behavior and engagement. A recent meta-analysis of temperament in childhood and preadolescence reported a large difference between boys' and girls' effortful control (Cohen's $d = -1.01$; Else-Quest et al., 2006). The authors concluded that girls have a stronger ability than boys to regulate their attention and inhibit their impulses – skills that certainly serve girls well in the classroom (Blair and Razza, 2007). It may be that group level differences between boys' and girls' behavior in the classroom is driven in part by boys' relatively slower developing regulation skills. It should be noted, however, that boys and girls do not differ substantially in their ability to resist temptation or susceptibility to distraction (Else-Quest et al., 2006; Silverman, 2003). Boys may, on the group level, have a slightly harder time regulating their behavior in the classroom, but developmental differences cannot explain all of the differences between boys' and girls' classroom behavior or achievement.

Socialization

Children come to understand gender in part through their experiences with gender socialization, which encompass both explicit and implicit messages (Maccoby, 1998). Accordingly, it may be that gender gaps in achievement develop, in part, from differences in the education-related socialization of boys and girls. As researchers, we know surprisingly little about the explicit gender-differentiated messages children receive about academics and occupations. We do know, however, from a recent survey of US adolescents that 54% of girls had experienced explicit academic sexism (i.e., reports of discouraging or other negative statements from others about their abilities in math, science, or computers because they are female; Brown and Leaper, 2010). Yet, the extent to which these explicit gendered messages influence achievement and explain boys' advantage in the areas of math and science is not clear.

In addition to explicit, sexist messages, socializers often influence children's views of gender, education, and occupations through more circuitous or implicit routes (e.g., Gelman et al., 2004; Langlois and Downs, 1980). Consider the domain of children's play activities. A large-scale meta-analysis of parental treatment of boys and girls found that parents who encouraged children's gender-typed toys and activities and discouraged cross-gender-typed toys and activities had children with more gender-typical activity involvement (Lytton and Romney, 1991). With regard to academics, mothers have been shown to provide more explanations of scientific content in a museum setting when talking to boys than to girls (Crowley et al., 2001), perhaps because parents view their sons as more competent in math as opposed to their daughters who they view as better in language arts (Eccles et al., 1990). Thus, parents may shape children's views about academics through the encouragement they provide to children to pursue gender-typed academic areas.

Similarly, teachers may influence children through their use of reinforcements in the classroom. Prior research has documented that boys receive more teacher attention (albeit generally in response to negative behavior), are called on to answer more questions, are interrupted less frequently, and receive more 'thinking time' and positive comments from teachers than do girls (AAUW, 1992; Hendrick and Stange, 1991; She, 2000). Even if teachers never make explicit comments about which gender is better at math, their differential treatment of boys and girls may negatively affect girls' motivation and interest in math and science, especially if they receive messages from others that boys are better in these subject areas. In addition to their use of reinforcement, teachers may also impact children implicitly through modeling; 76% of US public school teachers are women (NCES, 2010), perhaps sending a strong message to children that school is a place for girls.

Finally, it is worth noting that socialization has different effects on different individuals; while many women have reported being deterred from the areas of math and science because of negative gender-typed messages they received at home or school, other prominent female scientists, mathematicians, and physicians have reported being emboldened by negative messages and gender discrimination (e.g., McGrayne, 2001).

Gender Stereotypes

The limited research available on children's and adolescents' academic gender stereotypes suggests that from a young age, individuals categorize math and science as 'boys' subjects' and language arts and spelling as 'girls' subjects' (e.g., Plante et al., 2009; Rowley et al., 2007). Researchers have just recently begun to explore how these gender stereotypes about subjects may influence students' achievement and explain the gender gap. However, prior work on gender stereotypes suggests that the effects are powerful (Bigler and Liben, 2006).

The influence of the endorsement of gender stereotypes on students' achievement has been explored in studies examining boys' endorsement of masculinity stereotypes. Many stereotypes about masculinity (e.g., aggression, physical toughness, and emotional stoicism) are in stark contrast to the compliance and responsiveness required of students in the classroom. Consistent with the hypothesis that high endorsement of these stereotypically masculine ideals is negatively related to achievement, US middle-school boys with average levels of achievement tend to endorse traditional masculine stereotypes at a higher rate than boys classified as 'gifted' (Shepard et al., 2011). Similarly, extremely masculine gender-typed US boys are less engaged in school and have lower achievement than their less extreme male peers (Ueno and McWilliams, 2010). Endorsing stereotypes about masculinity – and behaving in those stereotypically-masculine ways – appears to be related to lower academic performance.

Importantly, mere *awareness* of gender stereotypes can influence youths' academic performance. Stereotype threat refers to the fear of confirming a negative stereotype and tends to arise when students who are confronted with a difficult task are aware of negative stereotypes about their group in the task's domain (Steele, 1997). In cases in which individuals are aware of a culturally-held negative stereotype about their group, they often become anxious that they will conform to the negative stereotype, and that anxiety leads to poor performance. So, for example, when college students are told that the math test they are taking has shown gender differences favoring men in the past, women perform worse than men. In comparison, when

students are told that the test has never shown gender differences in the past, women perform as well as the men (Spencer et al., 1999). Importantly, over time stereotype threat also has the potential to undermine students' identification with the relevant academic domain (e.g., Steele, 1997), which may explain some of adolescent girls' dampened interest in science, technology, engineering, and math (STEM) fields and boys' dampened interest in traditionally-feminine fields.

Interests

Finally, it is important to consider the role gender differences in interests may play in explaining gender gaps in educational outcomes. Children's preferences for gender-typed activities (e.g., balls vs dolls) emerge during the first year of life and continue into late childhood (McHale et al., 2004). Starting in elementary school, gender differences also appear in boys' and girls' interests in different academic subjects; for example, elementary school-aged boys have higher levels of interest in math than do girls – and the difference holds even when controlling for prior math achievement (Simpkins et al., 2006). At the same time, boys are more likely than girls to be interested in jobs stereotyped as masculine by their culture, such as jobs in STEM fields (Bigler and Liben, 2006), and the girls who are interested in male-dominated career fields in early adolescence often move away from these preferences – and toward female-dominated career fields – by adulthood (Frome et al., 2006). More work is needed to understand how these gender differences in interests develop (see Goble et al., 2012). However, as long as the gender differences in interest persist, it is likely that gaps will remain in boys' and girls' achievement and persistence in various academic areas.

Societal Responses to Gender Gaps

Over the last several decades, researchers, educators, and policy makers have responded to gender gaps in educational outcomes in a variety of ways. Many of these responses have in effect pitted girls against boys, rather than focusing on improving the academic achievement of all students. In this section, we discuss the movements focused on girls being shortchanged, boys being in crisis, gender differentiated and segregated learning approaches, and attempts to ameliorate gender gaps by reducing the focus on gender.

Identifying Gender Bias Approaches

Over the last several decades, many scholars have proposed that issues related to gender and education be addressed by focusing on the ways in which school systems are biased against one gender or the other. In 1992, the American Association of University Women (AAUW) spearheaded an effort to focus on the challenges girls face in schools. In *How Schools Shortchange Girls*, the AAUW drew on research to argue that schools needed to do more to confront the supposed sexism girls face in school. Perhaps as a result of these scholars' efforts, over the last two decades, researchers have focused on better understanding girls' experiences with sexism and discrimination in the classroom (e.g., Brown and Leaper, 2010) and developing interventions that encourage girls to enter STEM fields (e.g., Little and Leon de la Barra, 2009).

Some have labeled the argument that schools shortchange girls as 'false political propaganda,' citing gender gaps that actually favor females (such as grades in school and literacy scores; Kleinfeld, 1998). Indeed, in a movement developed in the late 1990s to focus on the challenges boys face in schools, scholars argued schools had gone too far in support of girls and were now hostile toward boys. The 'Boy Crisis' was born with books such as *The War Against Boys* (Sommers, 2000) and *Real Boys* (Pollack, 1998). Scholars began to argue that boys are falling behind girls academically in large part because they have begun to see school as a context more suitable for girls.

School systems have responded to these concerns. In the United Kingdom, the government supported the development of the Raising Boys' Achievement Project (see Younger and Warrington, 2006). In Australia, meanwhile, the government commissioned the report *Boys: Getting It Right* and is now funding Boys' Education Lighthouse grants to address boys' educational experiences (see Weaver-Hightower, 2009). Opponents of the boy crisis, in comparison, question whether the boy crisis movement is driven merely by concerns about boys' relative performance compared to girls – and boys' loss of status and power (e.g., Rivers and Barnett, 2006). These scholars point out that boys' educational achievement is generally improving overall; girls' performance is just improving at a faster rate. For now, camps focused on the challenges girls vs boys face in schools remain divided.

Gender-Differentiated Approaches

In recent years, there has been a resurgence in interest in gender-differentiated instructional approaches as a means to addressing gender gaps in education. Dozens of books marketed toward educators and the general public have been published with titles such as *Boys and Girls Learn Differently!* (Gurian et al., 2001) and *Teaching the Male Brain* (James, 2007). The instructional practices these books advocate tend to be based on gender essentialist beliefs, or beliefs that members of the same gender share inherent, unobservable, and meaningful similarities that cause observed gender differences in behavior between girls and boys (Gelman et al., 2004). For example, some of the authors argue that girls need cooperative classroom environments to succeed because they are often too sensitive for competitive environments, whereas boys need competitive classroom environments because by nature boys are competitive (Gurian et al., 2001).

The popularity of these gender essentialist strategies seem to be fueled, in part, by recent innovations in the field of neuropsychology. Neuroimaging studies have yielded new findings of gender differences (e.g., Baron-Cohen et al., 2005). For example, recent work has highlighted slight gender differences in hearing and the perception of pitch, which has been used to support a recommendation that teachers speak more loudly when talking to boys than when talking to girls (Sax, 2010). Neurologists, however, caution educators from changing classroom policies based on individual study findings; neuroimaging study results tend to be based on small sample sizes or effect sizes and are often highly tentative (Fine, 2010). Furthermore, there is likely within gender variability in hearing

and the perception of pitch for girls and boys. Accordingly, changing classroom policies to accommodate a finding at the group level might still be ineffective for some students.

Building on calls for gender-differentiated instruction, educators and policy makers around the world (and in Australia, the United Kingdom, and the United States, in particular) have begun to return to single-sex education, often in the form of all-girl and all-boy classes within coeducational schools (Younger and Warrington, 2006). Proponents of single-sex schooling believe that gender-segregated classrooms can help to ameliorate gender gaps in education by allowing teachers to use gender-differentiated instructional strategies while removing the distractions of other-sex peers (see Bracey, 2006). Opponents of single-sex schooling, in contrast, question the effectiveness of gender-differentiated instruction and worry that segregated classrooms increase students' gender stereotypes (Halpern et al., 2011). The debate about single-sex schooling is complicated by the difficulty in researching the effects of single-sex schooling on student outcomes. Single-sex schools are often schools of choice, and so there are both student and school selection factors that make it difficult to compare the effects of single-sex vs coeducation schooling (Bracey, 2006).

Gender-Blind Approaches

While some educators and policy makers have responded to the persistent gender gaps in education by focusing on gender, still others have argued for the opposite approach: deemphasizing gender. This approach comes out of intergroup theories that highlight the potentially derisive effects of highlighting gender as a social category (e.g., Developmental Intergroup Theory; Bigler and Liben, 2006). Deemphasizing gender as a category, these scholars argue, will reduce gender stereotypes, which, in turn, will grant students more freedom to pursue their academic interests and strengths without concerns about the 'gender-appropriate' approach (e.g., Bigler and Liben, 2012). A preschool in Sweden has put this perspective into action: the staff avoid the words 'him' and 'her' and instead refer to all children as 'friends' (Soffel, 2011). In the US, another intervention program is being developed with the goal of bringing girls and boys together. Program developers have taken the approach of discussing gender issues (such as bias and segregation) explicitly with teachers but have deemphasized gender in all discussions with children (Martin et al., 2012).

Future Directions

In the coming years, policy makers and researchers will continue to grapple with issues related to gender and education. In particular, further empirical work is needed that investigates mechanisms and developmental changes that may account for the changing educational gender gaps. For example, future work needs to examine the role of young children's gender-typed interests, and how those interests relate to their long-term educational outcomes, because we currently know very little regarding the degree to which children's interests motivate their performance in particular subject areas. Work examining the effect of changes in preferences and attitudes longitudinally would be particularly helpful in terms of identifying protective factors, risk factors, and mechanisms that relate to gender differences in educational outcomes. Although social developmental models have proposed pathways through which gender attitudes, stereotypes, and interests relate to educational outcomes (see, for example, Bigler and Liben, 2006; Ceci et al., 2009; Eccles, 1994), more data are needed to empirically support these theories.

Finally, in the coming years it will be particularly important to place issues related to gender and education in the proper context. As discussed, in many educational domains boys and girls are performing similarly (Hyde, 2005). Literature on stereotypes and stereotype threat also suggests that highlighting gender differences may serve to exacerbate gender discrepancies. Thus, care should be taken not to exaggerate the extent of the problem. Furthermore, researchers will need to pay particular attention to variations by nationality, race/ethnicity, and family income level. The gender gaps in the US, for example, are considerably larger among African-Americans and Hispanics than among Whites and, furthermore, the racial/ethnic achievement gaps (between, for example, African-Americans and Whites) are larger than any of the gender gaps in achievement (Freeman, 2005; Lee et al., 2007). Understanding the causes of these issues will require gender-focused researchers and policy makers to collaborate with experts from other areas of psychology and education.

Conclusion

In this article we have highlighted some of the critical issues related to gender and education facing policy makers and researchers. Although many of the traditional gender gaps in education have closed in recent years, discrepancies persist in areas related to achievement, attitudes, behaviors, and attainment. Several possible causes of these gaps have been proposed, ranging from gender differences in cognitive skills to differences in boys' and girls' socialization experiences and interests. Recently, educational programs have been proposed to address these issues and ameliorate the persisting gaps. In the coming years, researchers and policy makers will continue to grapple with how to best address the existing gaps, while also working to identify the causal mechanisms that may be affecting boys' and girls' chances for academic success.

Gender and Feminist Studies in Geography

Janice Monk, University of Arizona, Tucson, AZ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Gender and feminist studies in geography address the material and symbolic lives of women and men as they are shaped by aspects of place and social relations and how considerations of gender are implicated in the creation of space and place. Initially inspired in the 1970s by women's rights movements, geographers questioned the exclusion of women's lives from their disciplines' theories, methods, and practices. Since then feminist geography has introduced new themes by attending not only to binary distinctions of male and female but by addressing the intersections of gender with other sources of social difference such as age, class, race, sexuality, physical ability, and religion at multiple scales from the body to the global. Diverse methodologies are brought to bear as research, teaching, and engagement with community organizations have been influenced.

Gender and feminist studies in geography address the material and symbolic lives of women and men as they are shaped by aspects of place and social relations and how considerations of gender are implicated in the creation of space and place. Initially inspired in the 1970s by women's rights movements geographers questioned the exclusion of women's lives from disciplinary theories, methods, and practices (Monk and Hanson, 1982). Since then feminist geography has introduced new themes by attending not only to binary distinctions of male and female but by addressing the intersections of gender with other sources of social difference such as age, class, race, sexuality, physical ability, and religion at multiple scales from the body to the global. Diverse methodologies are brought to bear as research, teaching, and engagement with community organizations have been influenced.

Geography of Feminist and Gender Studies in Geography

In considering the nature and development of feminist and gender studies in geography it is important to examine where and by whom they are produced within and across national settings. Early work in Britain and the United States was central in initiating the field. Literature from those countries has continued to expand and to have high international visibility, but it is also striking to see the diversification of topical, conceptual, and methodological approaches. One indication of the scope is that in 2012 the Geographic Perspectives on Women (GPOW) Specialty Group (for further information on GPOW see the website www.gpow.org (last accessed 21 November 2012)) at the Annual Meeting of the Association of American Geographers sponsored 57 papers or panel sessions. Reflecting the setting, American geographers (mostly women) accounted for the largest number of presenters but international participation was also notable, especially from Canada, Britain, and several western European countries. Indicative of the wider interests in gender research, 20 of the sessions were cosponsored by other specialty groups, such as those on political geography, sexuality and space, qualitative research methods, and socialist and critical geography.

Gender research has also expanded substantially internationally. Involvement in the Commission on Gender and Geography of the International Geographical Union (IGU) (for further information see http://igugender.socsci.uva.nl (last accessed 27 November 2012)) reveals substantial interest in many parts of the world. The Commission has over 600 subscribers on its electronic mailing list and has regularly organized sessions at IGU Congresses, most recently in Germany (2012), Chile (2011), and Israel (2010). It holds or cosponsors focused events in other locations (for example, in Brazil and Singapore (2011), India and New Zealand (2010), Hungary/Romania (2009), and Taiwan (2008)). Twice a year the Commission publishes a newsletter with an extensive bibliography, archived on its website. Themes and approaches continue to offer points of contact between feminism and the three core traditions of the discipline identified by Susan Hanson (1992): finding significance in everyday life, appreciation of the importance of context, and thinking about difference, though practices reflect differences across places (Monk, 1994). Distinctions in theoretical orientations and methods of research were evident between early British and American work, for example, possibly more so than in later years as circulation of literature increased. British feminist geographers initially drew on socialist theorizing and the concept of patriarchy to examine women's position in labor markets, whereas work in the United States followed empirical and positivist traditions, documenting differences between women's and men's spatial behavior in, for example, daily travel patterns or migration. By comparison, Dutch initiatives emerged from student critiques of Marxist writing and relatively quickly turned to the applied and policy-related work that characterizes much Dutch geography. Joos Droogleever Fortuijn has since characterized the situation as balancing the margin with the mainstream in two respects: engagement with the dominant Anglophone work while working within Dutch traditions, and integrating gender content into mainstream teaching (rather than teaching separate gender courses in geography) while also collaborating in interdisciplinary programs such as international development studies (Droogleever Fortuijn, 2011). In Spain, early studies reflected a national tradition of rural geography and were empirically rather than theoretically oriented. Drawing

initially on census data, Spanish feminist geographers then turned to field research and qualitative methods in order to reveal women's linked roles in production and social reproduction. Subsequently Spanish interests have diversified to address gender in urban spaces, youth and immigrant communities, and aspects of the history of Spanish colonialism in North Africa as represented in women's travel writings (Diaz-Cortés et al., 2007). These trajectories partly reflected changes in the national context and partly the stimulus of Anglophone work, though recently there have been expressions of concern about Anglophone hegemonies and anxiety that these mask the situatedness of work in other languages and traditions. Spanish interests in gender are also unevenly located across academic spaces, centered at the Autonomous University of Barcelona.

The work of geographers associated with the IGU Commission on Gender and Geography reveals yet more diversity. In 2012, geographers in at least 45 countries were represented on its electronic mailing list, with strong representation from India, Spain, Italy, and increasingly from Brazil and Japan. In the latter case there has been more significant participation by male geographers than is common elsewhere (Murata, 2005). Representation is low in most Middle Eastern and African nations, China, and the former socialist nations of Eastern Europe and the Soviet Union. Economic, political, cultural, and linguistic diversity across contexts, scholarly traditions, academic structures, resources, and leadership are evident in the themes, approaches, and the extent to which feminist geography is taught. In Latin America feminist geography is more evident in Argentina and Brazil than elsewhere and is expanding rapidly in Brazil. Whereas their early studies focused on class and economic themes (Veleda da Silva and Lan, 2007), sexuality studies have recently emerged, accompanied by the creation of online multilingual (Portuguese, Spanish, English) publications. (See http://www.revistas2.uepg.br/index.php/rlagg (last accessed 27 November 2012).) As a consequence, work that previously circulated mostly to local audiences is now distributed internationally. Gender studies in India have faced barriers in school and higher education but are gaining greater international visibility partly as a consequence of a conference in Delhi in 2010. (Co-led by Anindita Datta (University of Delhi) and Kuntala Lahiri-Dutt (Australian National University) it attracted about 100 participants, primarily from India but also from southeast Asia, Europe, and the United States.) Publications from the conference include a special issue of the international journal *Gender, Technology, and Development* (Datta, 2011) while a recent book (Raju and Lahiri-Dutt, 2011) addresses the trajectories in gender studies in Indian geography as well as offering new research by local geographers. Empirical rather than theoretical studies predominate using both qualitative and quantitative methodologies, while attention to policy implications is especially evident following a national tradition.

With diverse international participation, gender studies in geography address many topical themes and employ multiple paradigms. Still, there are common strands, primarily the understanding of gender as a complex and varying social, cultural, historical, and geographic construction, not simply a binary biological distinction between women and men, that power relations are implicated in gender relations, and that space, place, and gender are interdependent. Additionally, research is not confined to studies on scholars' own national settings. There is a substantial record of research, especially on the global South, by scholars who are based outside the global South and undertake work in regions where feminist geography is not currently widely evident. (Examples of such geographers who have made sustained contributions are Sarah Radcliffe (UK) on political themes in Andean Latin America, Sylvia Chant (UK) on poverty in Latin America, southeast Asia, and west Africa, Janet Momsen (UK, Canada, and US), in the Caribbean and more generally on gender and rural development; Melissa Wright (US) on gender and violence the Mexico–US border and Ragnhild Lund (Norway) in development research and with consultancies especially in Sri Lanka, but also in India, China, southeast Asia, and Africa including collaboration with local colleagues.) Additionally, geographers in regions from which migrants originate are turning attention to gender and migration in receiving sites. (See, for example, the multiple studies by Nora Chiang (Taiwan) in Canada, New Zealand, Australia, and most recently collaboratively in Argentina. http://homepage.ntu.edu.tw/~cos/html/personalE_chiang.htm (last accessed 2 April 2013).)

Concepts and Themes

Since the 1990s, feminist geography has diversified not only as a function of its geographic expansion but also through engagement with interdisciplinary currents, especially with the linguistic turn in the social sciences that foregrounded discourse analysis. They have engaged with perspectives emanating from postmodernist, poststructural, and postcolonialist scholarship that questioned grand narratives and essentialism and that destabilized dichotomous categories such as man–woman, mind–body, public–private, and global–local. Much attention has focused on the concept of the body – as experienced, politicized, and portrayed symbolically in different spaces and times. Especially important has been awareness of intersectionality – the recognition that gender identities and experiences intersect with, among others, those of race, ethnicity, class, sexuality, religion, age–life stage, dis/ability, indigeneity, and citizenship. Attention to the construction of masculinities has also emerged and become a theme of growing interest. Further, it is recognized that knowledge and categories are situated in place and time, both for the researcher and for the people who are the subjects of research. While race/class/gender may be accorded primacy in some Western settings, some geographers such as Ghanaian Mariama Awumbila (2007), have noted that for African scholars foundational categories may include kinship, seniority, religion, and region. In India, caste and communalism as well as region are likely to be addressed. Concepts of place identification have also been complicated by the emergence of 'transnationals,' people whose lives are not bounded by a single place and time.

Some examples are helpful for illustrating the various ways in which these concepts have been taken up. Robyn Longhurst (2001), in her New Zealand context, has addressed multiple aspects of bodies ranging from responses to and restrictions on women's pregnant bodies in public spaces to reflections on the spaces of losing weight, the meaning of food for

migrant women and mothers' engagement with electronic technologies (for examples of such studies see http://www.waikato.ac.nz/fass/about/staff/robynl (last accessed August 10, 2013). Vidyamali Samarasinghe (2008) has contrasted the national contexts of Nepal, Cambodia, and the Philippines as sites of sexual trafficking of women. She highlights ways in which varying cultural values, economies, links to sexual markets, and national policies and relations shape different forms of exploitation of young women. Worlds away, Linda McDowell's (1997) multifaceted examination of the environment of merchant banking firms in London reveals how multiple aspects of discourses and bodily performances of masculinity and femininity (for example in speech and dress, class background, media representations of behavior, and assumptions of gender roles), limit women's opportunities for career advancement.

Awareness has also developed that identities and behavior can be fluid in their construction and expression with movement across different spaces, situations, and scales. Geraldine Pratt, for example, drawing on work by Alison Blunt, notes that the nineteenth-century British travel writer, Mary Kingsley, was constrained at home by her class and gender positions whereas in Africa, positioned by her white racial and class privileges, she seemed to abandon those restrictions and to move between roles identified as masculine and feminine. (For the many works by Pratt on intercultural experiences and collaborations see http://www.geog.ubc.ca/~gpratt/Site/Publications.html (last accessed 3 April 2013).) In a vastly different setting, Mary Thomas's (2009) research with teenage girls in a Los Angeles area high school also reveals the fluidities of situatedness. Identifying as Hispanic, Armenian, Filipina, and African American, the girls clearly recognized strong racial–ethnic territories at the school. Yet some also spoke of having friendships across those divides. Tellingly, however, expressions of friendship were spatially restricted, and could not be acknowledged in encounters such as in a shopping mall when the 'friend' was with a homogenous group of another ethnicity. Nor did these girls contemplate being present in the home of the friend. While expecting such limitations, their conversations nevertheless revealed hurt and discomfort with such situations.

Engagements with the complexities of gendered identities and inequalities across cultures, scales, contexts, time, generations, religions, and public, private, and emotional arenas of life have become a significant and recurring concern for researchers. They are very well illustrated by multiple studies of transnational processes' experiences in Singapore by Huang, Yeoh, and colleagues (see, for example, the multiple studies of diverse experiences of foreign-born women workers and their Singaporean women employers by Shirlena Huang (http://profile.nus.edu.sg/fass/geoslena/) and Brenda S.A. Yeoh http://profile.nus.edu.sg/fass/geoysa/ (last accessed 2 April 2013)) and by Japanese geographer Yui (2009). The national government policies have shifted from emphases on limiting population growth to ideas about eugenics and fostering childbearing by native-born educated and professional couples in order to stimulate population growth. Though local women may support larger family sizes in their responses to surveys, in personal interviews they discuss 'stopping at two.' Their participation in the workforce has prompted substantial reliance on foreign-born women, especially Indonesians, Filipinas, and Sri Lankans, for domestic help and child care. Those women's lives and choices are regulated by state policies as well as practices of employers. The long work hours required, together with control of and restrictions on spaces within the home, and incidences of verbal and physical violence from employers, disrupt the early feminist representations of separations between 'public' and 'private' spaces. Simultaneously, other groups of foreign-born women in Singapore, such as Chinese 'study-mothers' who accompany their children to Singapore, face limited employment choices, financial stress, difficulties in obtaining housing, and being stereotyped as sexual threats. In the Singapore offices of Japanese international businesses, yet another national group, young educated Japanese women, are valued as clerical workers for their language and culturally appropriate social skills but are restricted in their opportunities for upward mobility compared to their male compatriots. Their long-term opportunities for employment in Singapore are, however, limited as they approach their thirties when they also face prospects that they will no longer be considered employable if they return to Japan (Yui, 2009). Collectively these studies reveal how class, ethnicity, citizenship status, and cultural differences shape experiences in particular places.

Methodologies and Methods

From the beginning, feminist researchers critiqued assumptions exhibited in the methodologies and empirical content of mainstream geography with implications for its theories. Monk and Hanson (1982), for example, pointed out that research on migration with interviews of 'heads' of household generally presented men as key actors and decision makers and women as passive followers, despite an absence of studies confirming how decisions were made and the existence data that showed women as numerically dominant in migration streams at particular times and places. Urban travel models that dealt with the journey to work assumed full-time employment (implicitly male), rather than attending to the more complex patterns of part-time (usually female) workers, or of people combining responsibilities for household and paid work. To counter such limitations, feminists advocated attention to arenas more central to women's lives such as child care, housework, relations within work places, and women's fears in public spaces. To understand such themes they favored research methodologies, especially qualitative and in-depth investigations that would reveal how women saw their own worlds and that had the potential to modify hierarchical power relations between the researcher and those being studied.

As the research progressed a variety of methodological approaches emerged with much attention devoted to the politics of creating knowledge and recognition of its partiality in both senses of this word – that no story is considered complete or objective. Research aimed to contribute to the feminist agenda for social change. Challenges multiplied as studies crossed boundaries such as class, cultures, and national settings, and recognized the different priorities of the theorizing academic and of communities such as nongovernmental organizations. Reflections on such issues appeared quite early, for example in a series of articles in *The Canadian Geographer* in

1993 on the aspects of ethnographic methods and others on dilemmas in field work and qualitative research published in *The Professional Geographer* in 1994 and 1995. Concerns included approaches to collaborating with community groups across class and cultural boundaries and how and to whom research should be presented. Such themes were later explored in depth by Geraldine Pratt in the course of her sustained relationship with immigrant women at the Philippine Women's Center in Vancouver. She has complemented interview methods with participation in group activities such as role-playing and creating theater performances. Richa Nagar turned to collective writing and publication in both India and the United States in her projects with community women who were working against domestic violence in India. She also recognized that such collaboration involved local participants in managing differences among themselves and with nongovernmental organizations and that they faced social and economic risks and issues of backlash (Nagar, 2013).

As postmodernist and poststructuralist approaches became more widely integrated into feminist geography, methodologies expanded to include interpretation of discourses, including not only the language of interviews but also written and visual expressions in public documents, the press, fiction, travel writing, films, works of art, graffiti, and to experimental approaches such as autophotography and participatory video. Examples are well represented in the journal *Gender, Place and Culture*. Founded in 1994, this journal initially published two issues per year and has gradually expanded so that eight will be issued in 2013, signaling the growth of interest in space and place within feminist and gender research.

Methodological diversity is being further extended by use of the technologies of geographic information systems (GIS), whose use in feminist projects has been contested as being objectifying and contrary to feminist concerns with subjectivity. Feminist geographers such as Mei-Po Kwan (2002) with substantial GIS expertise, have, however, demonstrated that GIS is useful in examining fine spatial scales and for integrating time and space, and can complement qualitative and quantitative information derived from interviews or time diaries. Also drawing increasing interest are participatory action research methods. Though not unique to feminist studies, they are seen as a way of bridging the divide between theorizing and contributing to social change (Kindon et al., 2007). Employing more traditional geographic methods to serve feminist goals, yet another initiative has been the creation of atlases to demonstrate spatial patterns of gender and women's lives. They address themes not commonly mapped such as the incidence of domestic violence or engagement in unpaid work. In so doing, these atlases offer information of value for local and national agencies. Examples include the multiple editions of *The State of Women in the World Atlas* (Seager, 2009) and gender atlases of India (Raju et al., 1999), Japan (Takeda et al., 2007), and Switzerland (Bühler, 2001).

Putting Feminist Geography into Professional Contexts

Important concerns of feminist geographers have been the representation of women within the profession, to whom and how feminist/gender geography is taught, and bringing feminist geographic research into community life. The first of these initially gained wide attention when Wilbur Zelinsky (1973) addressed *The Strange Case of the Missing Female Geographer*. Subsequent accounts have addressed changes over time and place and explored the climate for women geographers in a number of settings, exemplified in a theme section of the *Journal of Geography in Higher Education* (34 (1), 2004) which illustrated patterns in Hungary, the Netherlands, Singapore, and Spain, and the experiences of women of color geographers in Britain, the United States, and Canada. Addressing trajectories from the nineteenth into the twentieth centuries and including women geographers outside academia, Maddrell studied women in British geography (2009), and Monk (2004) examined women in US geography. They took into account national, political, and social contexts and academic structures and cultures. One theme is the place of women in teaching and its implications for inclusion of gender themes and perspectives in the curriculum and pedagogy, for example, in field courses in higher education and in school-level geography. Most recently a section of *International Research in Geographical and Environmental Education* (20 (3), 2011) was devoted to the implications of neoliberal and postsocialist political regimes for opportunities to include gender-focused courses in university curricula. Articles on feminist pedagogy and teaching gender recur in the *Journal of Geography in Higher Education* (Monk, 2000).

Given the roots of gender studies in feminist political movements, it is also important to recognize that direct and indirect connections with and commitments to action in communities remain a commitment within feminist work. The creation of atlases and the application of participatory research methods (discussed above) are such expressions. So too are projects that involve direct collaboration with community organizations as in Geraldine Pratt's work. Other recurring engagements are the collaborations of geographers in Switzerland with community planning agencies, such as those of geographers with the equal opportunity office of the Municipality of Zurich to deal with uses of the public spaces of city parks (Kaspar, 2012). These projects combined research with public exhibitions and coverage in the press and media (E-mail, Elisabeth Bühler to Janice Monk, 8 July 2011). In Berne, such collaborations have addressed employment for migrant women involving members of the city's Gender Equality Board in leadership, workshops designed not only to gather research data but to assist women in developing their social capital, publications that take the form of recommendations to policy maker and nongovernmental organizations, and establishment of a mentoring project by the city government (E-mail, Yvonne Riano to Janice Monk, 11 July 2011).

Status and Emerging Directions

In a little over three decades, gender and feminist studies have become well established in geography and spread internationally, if unevenly, from their main origins in Britain and the United States. Their critical perspectives have contributed to reshaping epistemologies across subfields of human geography. Attention to gender and feminist geography is now

commonly found in texts introducing human geography, in compendia on trends in social, political, cultural, and economic geography including one devoted to feminist geography (Nelson and Seager, 2005), and in the reviews of directions in the discipline in the journal *Progress in Human Geography*. Nevertheless, there are still areas of the discipline where feminist scholars consider that attention needs to be strengthened. Though a feminist political ecology emerged in the 1990s (Rocheleau et al., 1997), resource management studies have recently been criticized for inadequate attention to gender (Reed, Christie, 2009) and for inadequate recognition of feminist perspectives in studies of global concerns about climate change and water resources (Elmhirst, 2011). While feminist geographies continue to focus primarily on aspects of women's lives, the work on bodies and sexualities certainly prompted new perspectives and widened related interpretations of gender across the discipline to include socially and culturally shaped masculinities, geographies of children and youth, race, and religion. There is every indication that gender and feminist studies will remain a vital field within geography and that this geographical work will sustain cross-disciplinary attention.

Abstract

In 2001, the Institute of Medicine (USA) called on biomedical researchers to step up their investigation of sex and gender as critical variables affecting health (Wizemann and Pardue, 2001). However, the authors also pointed out that the terms gender and sex have been used inconsistently and confusingly. While the definition of sex is relatively clear in that it is "the classification of living things, generally as male or female according to their reproductive organs and functions assigned by the chromosomal complement," the confusion seems to lie with the term gender that seems to have become almost synonymous with the word sex (Ristvedt, 2014). Gender refers to the socially constructed aspects of being female or male, i.e., the stereotypic psychological and behavioral characteristics presumably shaped by societal expectations (Haig, 2004). For future research it is mandatory that both aspects are investigated with a sound definition, which is acknowledged in the scientific and public discourse. Gender is of substantial relevance in every respect of health care and requires intensified research in basic and clinical areas, analyzing gender stereotypes and roles with respect to their influence in patient care, and checking for gender differences in research designs and results. Research evidence revealed that the field of health has to deal with numerous gender differences requiring not only an awareness in experts, clinicians, patients, and researchers for these differences but also a consciousness for more implicit gender influences exerted by each involved individual, being it researcher, clinician, or patient.

To be female or male is one of the most important biological determinants of life with critical consequences on many aspects ranging from cognitive and emotional behavior as far as human health (Wizemann and Pardue, 2001). Due to culture-specific gender norms and values, the distinct roles and behaviors of men and women give rise to gender differences. Gender norms and values, however, also implicate gender inequalities – that is, differences between men and women, which systematically empower one group to the detriment of the other. Both gender differences and gender inequalities can give rise to inequities between men and women in health status and access to health care (WHO, 2014).

As a consequence of Women's health movement and the feminist critique of science in the 1980s, the field of gender medicine evolved. Gender medicine is defined as "an unbiased comparison between women and men and the inclusion of gender as a socio-cultural process into medical hypotheses. It includes the recognition of biological sex differences among women and men, i.e., sex differences, but goes well beyond that" (Regitz-Zagrosek, 2012a,b). The subject of gender in health care has become even more prominent after 2000, with the increase in interest in biological differences between men and women and with the installation of specific centers for research in gender medicine, for example, in Vienna the Gender Medicine Unit at the Medical University, in Berlin the Institute of Gender in Medicine at the Charité, and in Stockholm the Center for Gender Medicine at the Karolinska Institute. Furthermore, gender interests are also represented within specific societies, such as the Organization for the Study of Sex Differences (OSSD) and the International Society of Gender in Medicine. General aim is to address women's and men's specific health issues in research and clinical practice to better understand and tackle the individual needs in health and disease.

Sociocultural and biological sex-specific influences exert their effects already in the fetus and are active lifelong. For example, lifestyle and fitness may lead to epigenetic modifications that not only affect the adult but also a potential developing fetus. Moreover, endocrinology and differential sex hormonal influences represent biological factors that affect structural brain development in the fetus but in addition to these organizing effects also have persisting major active effects that contribute to differences between men and women. And both these factors interact at every age and level, making it nearly impossible to exactly differentiate the influence of sex and gender, but rather taking into account the complex interaction in the field of health care and research (Haig, 2004; Rieder and Lohff, 2004; Ristvedt, 2014).

Gender and Medical Research

Up to the end of the last century, much of the human research has been performed in men, defining the male norm, and studies just neglected or failed to address specific gender differences. In the United States the Office of Women's Health Research at the National Institute of Health (NIH) achieved a change of the standard by which women as objects of research were excluded (Klinge, 2010), to be included in clinical research from 1994 onward. The same applies to studies on the pathophysiology of somatic or psychiatric diseases, which often show a marked difference in the prevalence for women and men. The divergent frequencies are also in most of the cases far from being clarified. In animal models, too, male animal models still predominate the field (Zucker and Beery, 2010). In 8 of 10 analyzed biological disciplines, authors found a significant sex bias in animal experiments, with a female bias only in studies on reproduction or immunology. Looking at the rate of female animals in studies of particular diseases, it emerged, that less than 45% of the studies on anxiety and depression used female animals, although these disorders have a more than two times higher prevalence in women. The same applies to drug studies on behavior, nearly exclusively performed in male animals, despite the fact that

absorption and effect rates are different in men and women. This is most often based on the assumption that female animals are less valid and reliable due to the estrous cycle, which has however been contradicted (Gold and Voskuhl, 2009).

The implications for human health care are obvious and perpetuate the gender bias. Zucker and Beery (2010) clearly voted for a correction of this bias by a refuse to tolerate it in publications and research applications. Other steps in that direction come from the formation of the OSSD in Washington DC (USA), and a new journal on the 'Biology of Sex Differences.' Certainly, adding female animals and humans to the research design not only makes it more complex and raises potential interaction effects, it also increases sample sizes and the number of influencing factors, that have to be taken into account, such as cycling phase. Based on the aim to advance the idea of personalized medicine we would like to stress that there is no way to neglect gender and its interactions in research, whatever the costs are, as it is one of our most formative factors in life. At the same time, this also ensures and increases the generalizability, quality, and validity of our research results and it guarantees equality in health care for men and women. As Ineke Klinge puts it: "Intriguingly, the nondiscriminatory proposition put forward by Gender Medicine is: to treat persons equally in health care often comes down to making a difference!" (Klinge, 2010).

Clinical studies face the fact that gender may affect the pathophysiology, the symptomatology, and the outcome of disorders, not overlooking the influence of gender stereotypes on behavior, as well as social gender roles and gender-specific environmental factors, such as prevention use, nutrition, stress, work, and lifestyle. Gender-specific behavior can initiate epigenetic changes, which are affected by estrogen receptors and finally may lead to differential results in male and female fetuses, which may determine gender-specific risk factors for certain diseases (Regitz-Zagrosek, 2012). Gender stereotypes and roles, for example, influence help-seeking behavior, with men seeking help less often and later (Möller-Leimkühler, 2013), and females showing a higher adherence to treatment and a different risk perception. Another very famous example is coronary heart disease (CHD), once highly associated to male gender and stress in managers, but now being acknowledged as one of the leading causes of death in women, with a differential symptom profile. This long neglected clinical field of relevant differences has produced a lot of research since its first discoveries and led to numerous relevant gender differences within CHD. In consequence, aspirin was established as a preventive measure for CHD, but this was based on trials with mainly male subjects. In the meantime, meta-analyses revealed that aspirin is effective in reducing the myocardial risk in men only, whereas in females it rather risks bleeding events (Berger et al., 2006).

Focusing on the specific needs and challenges in male health, it became obvious in a large EU project including 34 countries, that men have a higher mortality rate than women, that 50% of early deaths in men could be prevented, that CHD is still the main cause of death in men and men use preventive screenings less often than women. Moreover, depression and other mental disorders are underdiagnosed and not sufficiently treated in men (Bardehle, 2013). This shows that depending on where one sets the focus, on men or women, inequalities, and problems in health care arise in both. This should be addressed accordingly and where necessary in a gender-specific way.

Gender in neuroscience is another topic that merits attention (Cahill, 2006). Brain differences between men and women have been an issue neglected for a long time in neuroimaging research and sometimes even attacked since there has been a long-standing tradition, supported even by famous scientists, to use brain differences for the discrimination and to the disadvantage of women. In the last decades, the enormous potential of imaging techniques and their further development have led to a more specific characterization of the structure and the functional neuroanatomy of gender differences. Imaging studies shed light on neurobiological differences and potential influencing factors of the cerebral substrates of emotional and cognitive processes. An increasing number of recent publications on gender differences in neural correlates of different cognitive–emotional functions in healthy subjects demonstrate an augmenting interest in and acknowledgment of such differences. The number of studies on gender differences grew since then dramatically. Considering methodological differences and study constraints, oversimplifications and overinterpretations have to be avoided and interpretations have to be made with caution. The recognition of structural and functional cerebral differences may however have clinical implications with respect to individually optimized diagnoses and therapy of disorders.

In this field we are also embedded in a controversial discussion on biological determinism vs individual experience affecting the brain. We would like to stress the view, that behavior and brain are closely intertwined and as such, not only behavior, but the brain too is a product of biological influences as well as environmental experiences in their interaction. There are numerous findings to support this view plus we have to acknowledge the enormous plasticity of the brain over time. We always only assess a momentum of its structure and function, but the brain is subject to continuous dynamic changes again stemming from biological (i.e., aging) as well as environmental individual sources (i.e., training). The brain shows sexual dimorphism in structure, with a larger volume and a higher percentage of white matter and cerebrospinal fluid in men (overview in Habel and Derntl, 2013) whereas women reveal a higher rate of gray matter. However, the direct relationship between brain structure and function is still unknown and the same applies to brain–behavior relationships. The fact that there are no behavioral sex differences does not automatically imply that there are no brain functional differences and vice versa. Such functional gender differences are often a matter of debate due to contradictory results and have indeed a number of methodological challenges (see Ihnen et al., 2009). One example is, that is has often been stated, that women show better verbal abilities and this may be based on a differential functional lateralization. This stimulated a number of imaging studies with quite equivocal results. First, looking at this verbal superiority in greater detail, neuropsychological findings most often show a functional superiority of one or the other gender only restricted to certain subfunctions and not to more general abilities. The frequently held assumption, that language functions are less lateralized in females could finally not be supported by a large meta-analysis on 14 studies from 1995 to 2004 (Sommer et al., 2008). Besides cognitive abilities, the same

inconsistencies can also be found regarding emotional functions (Kohn et al., 2011; Derntl et al., 2010). In the meantime the growing interest in gender differences risks to provoke a publication bias with a higher probability for publication of studies on gender differences, which in turn strongly impacts on researchers to stress such differences.

Hence, these research examples show that much effort has been put in reducing the inequality, but still there are a number of challenges that have to be tackled. Gender and sex differences have to be taken into account in all domains of research, from basic animal research to neuroscience and public health, and also in data analyses and interpretation of results. This has been already stressed in the EU policy for research, acknowledging and pointing the attention to the fact that biological mechanisms, causes, clinical manifestation, consequences, and treatment of disease and disorders often differ between men and women being the topic of several calls starting with the Framework Programme 6 (2002–07). It is however also mandatory to promote the distribution of knowledge on these gender and sex influences to experts and the public.

Gender and Health Care Users

Whether the patient's gender leads to differences in treatment is still a matter of debate. Both, the structure of the medical interview and the treatment of similar medical problems may be affected by gender of the patient. Research comparing different aspects of physician communication observed that female patients have more contacts in general and more interactions characterized by in-depth talks compared to male patients (Bertakis et al., 2003). Studies analyzing pharmacological interventions found an undertreatment of women in the field of cardiology, especially concerning heart failure (Baumhakel et al., 2009) as well as CHD (Bischoff et al., 2006). Further, studies showed that female patients obtain less evidence-based medical therapy and fewer investigations such as coronary angiography in case of stable angina and coronary disease (Daly et al., 2006) as well as laboratory tests (Hamberg et al., 2002). In contrast, diagnostic support of physiotherapists and orthopedists were more often recruited for female patients (Hamberg et al., 2002). This tendency seems to be influenced by gender-specific expectations and perceptions creating a priori assumption about the needs of the patient.

Research in dental offices also has shown that the physician–patient interaction seems to be influenced by gender stereotypes and gender identities in both directions: Considering the percentage of total talk, the gender-specific patient–physician interaction ranged from the lowest percentage for male gender–concordant interactions to the highest percentage in female gender–concordant interactions. Interestingly this did not affect the patients' satisfaction with the physician (Peck and Denney, 2012).

Gender and Health Care Providers

According to several studies, female and male health care providers differ in practice styles with potential implications for patient health care use and mortality. For example, female physicians show a more patient-centered communication style by devoting more time to aspects such as psychosocial counseling, providing encouragement and reassurance as well as social exchange (Bertakis et al., 2009). In their review article, Roter and Hall (2004) conclude that data from the few previous studies on the effects of physician gender on the health care process indicate that female physicians spend more time during a typical visit talking with their patients than do male physicians. During this time, they engage in communication that more broadly relates to the larger life context of the patient's condition by addressing psychosocial issues through related questioning and counseling and through greater use of emotional talk, positive talk, and active enlistment of patient input.

In contrast to the higher levels of psychosocial and socio-emotional exchange, there is little evidence that physician gender is related to the more task-specific communication elements of care. Moreover, the authors point out that results from previous studies do not suggest that physician gender was related to the provision of biomedical information (including discussion of the diagnosis, prognosis, and medical treatment).

There is an ongoing debate whether female physicians are more likely than men to provide certain morbidity- and mortality-reducing preventive services to women. While some studies observed this effect particularly in cancer screening, for example, use of mammography (e.g., Franks and Bertakis, 2003), very recent data however indicate no significant association of gender of health care provider and health care utilization or mortality (Jerant et al., 2013). The authors speculate that the heterogeneity of findings might be based on the different methodological approaches as they relied on a huge sample of the US national data and used adjusted analyses of prospective data.

In sum, both patient and physician contribute to differences in health care by their gender-specific expectations. Subsequently, gender differences have significant consequences on medical practice and therapy effects. This does not mean that men and women are always treated differently or should be treated differently; studies just endorse that gender expectations are present.

Regarding the working conditions and their impact on health and well-being of health care providers, recent data indicate that high work load and work stress particularly affect female and older physicians (Fletcher et al., 2011). Especially mental health issues, ranging from burnout, depressive mood to suicidal thoughts, are a more frequent consequence of work stress and long working hours in female than male physicians (Hayasaka et al., 2007). This, however, seems to be influenced by discipline; for example, female surgeons report more work overload and are less satisfied with their work compared to female internal specialists (Bergman et al., 2003). Besides discipline, the work setting also seems to influence work satisfaction and stress response. Several studies indicate that the physicians and nurses working in intensive care units are specifically prone to developing depressive symptoms and burnout, and being female seems to increase the risk (Michalsen and Hillert, 2011).

Research suggests that empathic engagement in patient care can lead to positive clinical outcomes by improving quality of

life and reducing emotional stress (e.g., Hojat et al., 2013). More than 10 years of studies on empathy in medical students and physicians indicate that empathy tends to erode during medical school and in residency training (Neumann et al., 2011). Furthermore, higher empathy scores have been linked to better ratings of clinical competence in core medical school clerkships and interest in primary care specialties that often require first-encounter and long-term face-to-face interaction with patients (Hojat et al., 2002a). Of note, female medical students as well as physicians reported significantly higher empathy scores than males (Hojat et al., 2002b), which corroborate findings from empathy studies outside the health care system (Derntl et al., 2010). On the other hand, recent findings from Hojat et al. (2013) indicate that empathy can be enhanced and sustained in female *and* male medical students as measured via self-report questionnaires.

Conclusion/Outlook

Our overview illustrates that bringing gender in the last decades into the focus of health care and research has had beneficial effects with respect to an optimized personalized patient care. It also created an awareness of the topic and advanced the field and knowledge on the gender-specific pathophysiology, symptomatology, and illness course for different disorders. Although a number of achievements have been accomplished there is still a lot more to do, to minimize gender inequality in health for patients, clinicians, and researchers.

Gender and Language: Cultural Concerns

Ruth Wodak, Lancaster University, Lancaster, UK

Abstract

Research on gender and language started in the United States in the late 1960s and early 1970s and quickly took off across the Western World. At that time it was closely linked to the women's liberation movement and had many practical implications such as the creation of guidelines for nondiscriminatory language behavior for official purposes in bureaucracies, media, publishers, and so forth. There are many different theoretical and methodological approaches, which also imply a range of differing ideological positionings. Currently, in the twenty-first century, we encounter an important focus on more critically inspired work and on the integration of various dimensions such as social class, gender, ethnicity, and so forth in the actual empirical investigation, an approach termed intersectionality. Moreover, the performative aspect of social and thus also gendered language practices is increasingly salient.

Setting Out the Problems

Research on gender and sex in sociolinguistics and discourse analysis started systematically in the early 1970s, probably as a result of women's liberation movements. Investigators examined two domains of language behavior in particular: speech behavior of men and women on the phonological level, and interactions (conversational styles) between women and men in discourse (for overviews and the history of the field see Hall and Buchholtz, 1995; Crawford, 1995; Harrington et al., 2008; Holmes and Meyerhoff, 2003; Kotthoff and Wodak, 1997; Lazar, 2005; Mills, 2004; Sunderland, 2004; Talbot, 1998; Wilkinson and Kitzinger, 1995; Wodak, 1997; Wodak and Benke, 1996).

Studies of gender-specific language behavior depend – as does all research in the social sciences – on the authors' implicit assumptions about sex and gender, methodology, and samples used, etc. For example, some studies suggest that women use more standard language than men because they try to adapt to social norms (Trudgill, 1974). On the other hand, other large-scale surveys have shown that young women tend to speak dialect and nonstandard language as well (Wodak, 1984), due to specific situations like family conversations and peer group talk.

The socialization of infants is often regarded as primarily the duty and work of mothers; mothers use 'motherese,' a very specific conversational style adapted to the needs of infants; as a result of caretaking, children acquire the regional dialects and vernacular, which their mothers use at home. Other investigations illustrated that professional women are under more pressure than their male colleagues; therefore they adopt high standard sociolects or even hypercorrect features (see Kerswill, 2012). However, hypercorrectness is also clearly related to social class: Working-class and lower-middle-class men also tend to speak hypercorrectly in certain organizational contexts (Wodak, 1996). Very detailed case studies of code switching, moreover, have shown that the use of either standard or nonstandard styles as well as minority and majority languages depends highly on the context of the utterances as well as on social class (Duchene, 2008; Martin-Rojo and Esteban, 2003). Nonstandard lects can also be the manifestation of certain political opinions and attitudes as in the case of Ebonics (see Baugh, 1999), i.e., 'African-American vernacular.'

The same variation of correlations is true for studies on conversational styles: In some cultures, men clearly interrupt women more frequently and dominate topic choice, but in other cultures this need not be the case (see Sunderland, 2004). As a result, women's language has been said to reflect their conservatism, prestige consciousness, upward mobility, insecurity, deference, nurturance, emotional expressivity, connectedness, sensitivity to others, solidarity, and men's language is heard as evincing their toughness, lack of affect, competitiveness, independence, competence, hierarchy, and control (Eckert and McConnell-Ginet, 1992: p. 90). Of course, many differences are due to cultural variation as well which has to be accounted for. Many empirical studies have, however, neglected the context of language behavior and have often analyzed gender by merely looking at the speakers' biological sex (see the arguments in Wodak and Benke, 1996). By focusing only on the biological sex, the whole group of women is perceived as homogenous and contrasted to the whole group of men – also perceived as homogenous – without taking differences in these groups into account (see below).

Such a dichotomization clearly does not make sense when looking at many studies, which have shown significant differences that occur with women or with men due to culture, social class, ethnicity, etc. (Wodak and Schulz, 1986; Kotthoff and Wodak, 1997). Moreover, gender is related to and overlaps with the sociocultural and ethnic background of the interlocutors, with their age, their level of education, their socioeconomic status, their emotions, and the specific power dynamics of the discourse investigated. The focus nowadays lies on the discursive construction of identities in interaction where gender is but one part of this attempt (Kotthoff, 2010; Pavlidou, 2010; Wodak et al., 2009). Thus, research on gender should take the whole interaction and context into account; of course, the biological sex will always be part of a categorization but other categories might prove more valid in a specific research that makes it possible to operationalize gender roles (the inclusion of professional roles and organizational roles with gender is of utmost importance as well as culture and ethnicity; the socialization of women who come from Islamic cultures is

obviously different than the background of Western European women so that intercultural problems clearly arise in interactions, see Hellinger, 2010). All these results suggest that gender has an enormous impact in many relevant situations, like schools, hospitals, courtrooms, etc., but only in combination with other variables; this phenomenon is called *intersectionality*. However, it is usually not possible to try to decide which variable generally would have more impact. Only very detailed qualitative studies can provide insight into such complex theoretical questions (Wodak, 2008).

Important Theoretical Developments in the Field

Different models of *gender* have influenced theorizing and methodology over the years. The 'dominance' *and* 'difference' studies of the 1970s and 1980s saw gender as 'differential tendencies' between women and men, boys and girls. Whereas investigations following the 'deficit model' have interpreted the use of such indicators as manifestations of 'powerless language of women,' research in the paradigm of the 'difference model' views the linguistic behavior of men and women as originating in opposed modes of socialization and equal in their meaning and impact (Tannen, 1994). Hedging, tag questions, or indirectness can be viewed 'negatively' or 'positively,' either as signs of female insecurity or as supporting conversational work, depending on the context of the discourse and the theoretical approach adopted. This controversy led to many polemical debates, which finally illustrate the invalidity of such dichotomous distinctions. Thus, nowadays, other research questions have become more important, viewing gender as constructed due to *context*.

Social constructionism, however, sees gender as linguistic dealings *with* (individual, and groups of) women, men, boys, and girls, for example, how they are addressed, what is said *to* them and, more importantly what is said and written *about* (individual, and groups of) women, men, boys, and girls. The first understanding is arguably the 'popular' understanding of gender, the focus being on *who* (speaker sex) and *how*. The second two, however, de-emphasize gendered speakers (and writers) as agents, focusing rather on *what* is said (written) *to*, and especially *about*, women, men, boys, and girls (Pavlidou, 2010). Importantly, it was *poststructuralist thinking* more generally, associated with social constructionism that allowed gender to be seen as something *talked and written about* (as well as enacted in interaction), and thus as a *set of ideas* (rather than something embodied), hence an ideology, a set of values and norms, and simultaneously, frequently sexist stereotypes. Indeed, the gender differentiation *constructed* in talk or writing (i.e., the substance) may be more significant than any stylistic or interactional gender differences in language use (see Kotthoff, 2010). Most gender and language studies today encompass the last two meanings of *gender* together with the nuanced version of the first. It thus evidences poststructuralist characteristics, in that its concerns are (see Cameron, 2005): (1) gender diversity (e.g., class, ethnicity, and how these both interact with gender; multiple masculinities/femininities; differences among 'women' and 'men'); (2) gender being 'performed' (see below) in an ongoing way, allowing for *agency*; performance being achieved partly through language (which is therefore *constitutive*); similarly, power being 'done' rather than something speakers 'have'; (3) 'local' or 'contingent' explanations for gendered language patterns and the importance of specific contexts.

The notion of *performance* (Butler, 1990) originates from the field of philosophy. Judith Butler has been very influential in the gender and language field, and we now read about gender not only being constructed and performed through language, but also *accomplished*, *achieved*, *enacted*, and *effected* by language. 'Local' or in-context explanations for gendered language patterns have increasingly been framed in terms of *Communities of Practice* (Lave and Wenger, 1991). Communities of practice are defined as "(a)n aggregate of people who come together around mutual engagement in some common endeavor. Ways of doing things, ways of talking, beliefs, values, and power relations – in short, practice – emerge in the course of their joint activity around that endeavor" (Eckert and McConnell-Ginet, 1992: p. 95). Gender identity is produced, reproduced, and also contested through participation in such communities, in particular through engagement with gendered practices. As Litosseliti observes, the communities of practice notion allows us to "distinguish between speakers' assumed gendered behavior and the range of identities available in the gendered communities that speakers inhabit" (Litosseliti, 2006: p. 66; see Wodak, 2011 about communities of practice to which Members of the European Parliament (MEPs) belong). While researching gender, the emotions, attitudes, values, intergroup, and intragroup relationships have to be accounted for as well. Eckert and McConnell-Ginet studied peer groups of girls and boys and could illustrate why big differences on a phonological and conversational level occur between two groups due to all the above mentioned factors. Eckert and McConnell-Ginet argue very convincingly and provide many examples to support their view that survey studies are too general and their level of abstractness are too high because all the important sociological and psychological parameters cannot be integrated. Moreover, and this criticism applies to survey studies in general about other topics as well (e.g., research on anti-Semitism and racism, Wodak et al., 2009), questionnaires and opinion polls usually manifest self-assessments of the interviewees. A bias due to education must be considered as well: Better-educated interviewees usually know what kind of answers is expected from them (e.g., Wodak et al., 2009). They answer accordingly even though this might not be their opinion at all. This bias is very important in all studies related to stereotypes and prejudice research. Therefore, such quantitative studies must be complemented with qualitative case studies using authentic data tape-recorded in everyday interactions as well as ethnographic observations (see Titscher et al., 2000).

Sexism and the Language System

Analogous to the term 'racism,' the word 'sexism' was invented in the 1960s. It refers to discrimination within a social system on the basis of sexual membership. With the concept of 'sexism,' women defined themselves for the first time as a suppressed minority expressing basic political interests of being judged and valued in equal terms as men. Of course, the history

of women's fight for equal rights is much older (see Saurer, 2014) but the political movements in the 1960s, together with innovations like the invention of the contraceptive pill and birth control on a larger scale started a qualitative new time for women's emancipation. As such, they sought to reveal the mechanisms of suppression, making others aware of and fighting these devices. Social groups often define themselves by means of their common language, which plays an important role in identity creation and, for subcultures, serves as a means of differentiating themselves from the outside world. This specific identity manifests itself in certain conversational styles, manifestations of emotions, etc. (see Coates, 1997; Buchholtz et al., 1999).

Feminists conceive language as "a symbolical reflection of androcentric structures" (Günthner and Kotthoff, 1991: p. 7), as one of the means of patriarchal society to discriminate, disregard, and incapacitate women. In their view, language systems already reflect the patriarchal structure of Western societies. Such an assumption manifests a basic consideration of sociolinguistics, namely that language and social norms are connected and that language manifests and also constructs social practices (Wodak, 2008, 2011). If this claim is accepted – and such theories stem from Wittgenstein's 1967 concept of 'language games' – then the manifestation of women's domination must also be manifest in language.

The assumption that an individual language system has lexical elements and morphological and grammatical rules that are already sexist is based on the premise that "due to their long history as public decision makers, men not only determine the economic, political and social orientation of social life, but also influence the functioning and the semantic contents of each individual language" (Postl, 1991: p. 89). Once the language system has become the object of investigation for feminist linguists, it is interesting to note how the linguistic structure of an individual language is connected to the structure of society, how the structure of the language is conditioned by the structure of society, and vice versa. Unlike studies investigating divergent gender linguistic behavior, studies on the sexist use of language focus on the possibilities of reference to both genders or their practice that exist in an individual language. According to Pusch (1984: p. 7), the objects of 'feminist system linguistics' are 'patriarchalisms in diverse language systems.'

Feminist Linguistics

According to Hellinger (2010), feminist linguistics (FL) is distinguished from all other disciplines by the following three aspects, which similarly analyze the relationship between language and gender:

1. FL places female and male linguistic behavior and the linguistic phenomena connected with the designations of women and men at the center of its considerations.
2. FL interprets person-related asymmetries in the field of language systems and language use, as expressions of the linguistic discrimination of women (sexism) and links these directly to the plane of social discrimination. Traditional studies usually make do with descriptive results. Clearly, different languages necessarily differ in their linguistic realizations of such inequality: In German or Polish, for example, suffixes and certain prefixes manifest gender. Kargl et al. (1997) have submitted a whole register of possibilities of equal treatment of women and men in many everyday genres in communication, starting with names and labels up to whole reports in newspapers, as well as conversations. These attempts are valid in written as well as oral speech and have led to huge debates in the media (see Hellinger, 2010); in German, specifically, the use of capital 'I' in written texts was at the center of such political discussions (i.e., '*Lehrer-Innen*' vs '*Lehrer*' and '*Lehrerinnen*' or '*Lehrer/innen*').
3. FL does not accept phenomena as given, but seeks alternatives in keeping with the principle of the linguistic equal treatment of women and men. It pursues explicitly political goals by criticizing ruling linguistic norms and understanding the linguistic change it advocates as part of an overall change in society.

Sociolinguistic Studies of Sex/Gender

In the 1970s, 'sex' was established within sociolinguistic research as a social variable next to the already existing variables of social stratum, age, nationality, ethnic affiliation, religion, class, and region. In correlative-quantitative sociolinguistic investigations on the prestige and stigma variants of languages (see Kotthoff, 1992), the sex variable became a factor which significantly affected the use of language. The best known representatives of this quantitative-correlative approach in sociolinguistics, with its focus on urban groups of persons, are William Labov, Peter Trudgill, Lesley Milroy, and Paul Kerswill. The working methods within this sociolinguistic approach diverge considerably from one another in certain aspects (such as endorsing correlationist sociolinguistics or network analyses, and so forth) but in one respect they are identical: All of them operate quantitatively, that is, linguistic variables are defined that are realized in different forms in different varieties. Then, the different variants are correlated with sociological parameters (Kerswill, 2012).

Several other studies have taken different approaches and have used new and other methodologies. In particular, a lot of criticism related to the implicit chauvinistic ideologies in these first studies and also to the undifferentiated analysis of the two sexes, which totally neglected the range of variation in each of the genders under observation. In a study of the language of mothers and daughters in Vienna, for example (Wodak, 1984; Wodak and Schulz, 1986), it could already be proved that, apart from these sociological parameters, other variables, such as psychological ones, are also responsible for the variation concerning each gender. This study stressed in particular the variation that was found among the women and girls investigated, one that relativized the factor of 'sex.' It could be shown that mothers with a positive relationship to their daughters spoke differently than mothers with a conflicting relationship. The same is true for the daughters (30 mother–daughter pairs were interviewed and tested). These results illustrate that emotions and relationships as well as educational styles and the content/discontent of mothers are more important than social class in an isolated way. Moreover, this study proves

that the differences in one category of sex can be statistically significant due to all these parameters.

Such results and tendencies are of utmost importance for the – frequently controversial – debate on gender and sex as well as social class. First, it could be shown that significant differences exist in one category (either women or men). Second, many assumptions about the differences between working-class and middle-class socialization could be contradicted – educational styles do not vary so much by social class but more by the self-assessment of mothers and their attitudes to their own life and achievements. Third, it could be shown that no significant differences appear between mothers who work at home and mothers who have professional lives outside of their homes. Therefore, many claims that children need mothers who only stay at home are wrong; the satisfaction of women with their own lives is the most important factor that affects their relationship with others, in their families, or outside of their homes. Fourth, generalizations about the use of vernacular and dialect could also be contradicted: Even daughters from upper-class families used Viennese dialect to distinguish themselves from the phonological styles of their mothers and to be able to manifest their autonomy. This study illustrates the necessity of a very complex and interdisciplinary approach to gender research. Currently, the complex relationship between social class, gender, culture, communities of practice, and so forth are termed as *intersectionality* (Sunderland et al., 2013).

The Analysis of Conversation and Discourse

Unlike the above mentioned research field, FL – which examines the use of language – concerns itself with gender differences in conversation and discourse (oral as well as written). Differences are investigated in the following domains of language use: voice, pronunciation, intonation, choice of words, argumentation, lexicon, syntax, interactional and conversational behavior, as well as visual features and modes and nonverbal communication. The gender-induced differences in the use of language are not treated simply as divergent variants standing side by side. Due to a patriarchally organized society, the interpretation of the differences ascertained is of major social and political significance. Research on African communities and their gendering as well as the intersectionality have hugely broadened our perspective (Sunderland et al., 2013). Moreover, research on successful women (Wagner and Wodak, 2006) and female leadership (Baxter, 2006) are drawing our attention to women who 'seem to have made it'; that is, who have achieved high status positions in their professions. It is important to discuss which factors might be of relevance for such trajectories and what the context-specific costs and benefits might be.

Recent Theoretical Approaches in the Feminist Study of Discourse

The Construction of the 'Sexes'

In her arguments against the tenability of the categories of 'woman' and 'sex,' Judith Butler refers to postmodernist theories (Butler, 1990). In the manner of Foucault she ascribes normative power to the idea of gender identity and the attempt to describe it. By the mere act of defining a gender identity, many bodies, practices, and discourses are excluded or devalued, whereas the constructed character of this gender identity is simultaneously concealed.

Thus, in such feminist theories (Butler, 1990), the idea of two sexes is criticized as being a construction, a prediscursive factor taking the place of reality. Following this interpretation, 'sex' cannot be separated into a biologically inherent aspect and a socially acquired one. The category of 'sex' itself, in Butler's view, is a purely cultural product of discourse. Such an opinion relates well to Foucauldian theories of discourse. 'Sex,' therefore, cannot be viewed as a universal, suprahistorical and extrasocial entity, it is understood to be an "integral component of every form of life" (Butler, 1990: p. 23). Such a view relates well to the assumptions of context sensitivity discussed above. On the other hand, 'sex' possesses a material basis: In many relevant contexts in our societies, women and men are still evaluated, judged, promoted, or paid according mainly to their biological sex. These facts are not accounted for in Butler's approach. More recently, some authors have differentiated Butler's dogmatic position: It is a question of revealing "the reproduction mechanisms, networks, and institutional compulsions that ensure that constructions become persistent and resistant and appear timeless, immovable, and identical with themselves" (Hirschauer, 1992: p. 333). It is a matter of exposing the arbitrary construction of this binary opposition and hence also its mutability, and not of criticizing the binarily organized perception as unreal.

Doing Gender

Unlike a research approach that accepts sexual differences as an aggregation of qualities and deals with the qualitative behavioral tendencies of women and men, ethnomethodologically oriented studies produced a new focus of research: 'doing gender' (Kotthoff, 2010). Such an approach complements traditional theories, which viewed gender as an aggregation of static attributes and are concerned with investigating and displaying the peculiarities of women and interpreting them as 'gender-specific' or 'gender-typical' attributes so as to reveal the asymmetry of the difference between the sexes, to criticize it, and to make it politically visible. The use of a bundle of characteristics and attributes to define gender complicates or renders an impossible interactional approach since attributes are 'entities' and not processes. This concept entails that definitions of gender cannot change, transform, and are not influenced by, spontaneous interactions. A further problem raised by the concept of gender as a concept of attributes is the possibility of individualization; that is, the individual who has been seen to possess or not to possess certain attributes becomes the center of focus, and the level of the social system is neglected. Unlike this non-interactive approach, 'doing gender' regards membership of a sex not as a pool of attributes 'possessed' by a person, but as something a person 'does.' In this sense, membership of a gender constitutes a performative act and not a fact. Gender is continually realized in interactional form. Gender is created not only in the everyday activities that characterize 'doing gender,' but also in the asymmetry

of the relationship between the sexes, the dominance of the 'male' and its normativeness. Patriarchal inequality is produced and reproduced in every interaction. This concept of 'doing gender' stresses the creative potential and the embedding of gender-typical behavior in a social context.

Female MEPs, for example, have created very different ways of positioning themselves in interactions with male colleagues in the European Commission or in the European Parliament itself. Interviews with female MEPs (Wodak, 2003, 2004, 2011) illustrate that they are very conscious of their gender roles and that they tend to construct different ways of self-presentation in interactions: in particular, one MEP stated the following, in talking about her first experience as a rapporteur.

> when I – entered the parliament – *Orientation* (lines 1–3) on my first report it was about Leonardo I don't know if you know: ((laughing)) well – I said 'I'm going to speak to the commissioner' and – I – /I knew – he only speaks very bad French and my er my French was very bad as well. so I said 'I want to have interpretation' So – I went to the commissioner *Complicating Actions* (lines 4–14) with a very good int/int/interpreter and I/I/I/I talked more than an hour with him. because we talked the same about it and at the end he said – 'well: I have here the advice of my: civil servants but I – agree with you:
>
> and this and this and this all goes through – ' so you have to be: – er – I don't know/how do we call it in English in / in the Netherlands we say [brutal] so you have to: ((laughing)) be polite *Evaluation* (lines 16–20) but you have to – you:/you mustn't be/ you mustn't *sit* behind your -/your *desk* – because that doesn't help. ((laughing)) but then then you have the worse system that I tried several times *Coda* (22–31). …

In this example, which has been marked for basic narrative structure according to Labov and Waletzky's (1967) model, we see that this MEP's story is objectively about having a successful meeting with a Commissioner while acting as rapporteur on a report about Leonardo – an EU youth and education related program established in 1995 to provide financial support for professional development and job training. In lines 4–6, the complicating actions, she shows how she went to the commissioner with an interpreter, and because she and the commissioner had the same understanding of the issues involved, he was willing to support her, despite contrary advice by his 'civil servants' on the matters involved. The main point of the story, or evaluation, from the MEP's perspective, is to show that as an MEP, to get things done, you must be active and assertive, 'not sit behind your desk.' Thus, in this narrative, she positions herself as an MEP who is proactive and who will do what it takes, including arguing directly with Commissioners, to see that her voice is heard. She also orients to being a rapporteur (line 2), which carries some responsibility in a committee, and to being from the Netherlands (line 17), although this last identity is evoked only to characterize her style of work ('brutal' in Dutch, or 'assertive') (for further details of the analysis see Wodak, 2011). This narrative also manifests the complexity of the European Parliament, the interwovenness of languages, cultures, positions, political affiliations, and gender roles, as well as professional experiences.

Another of the interviewees is oriented to a particularly wide range of identities (left, woman, Swedish, mother, political outsider, etc.) during her interview. Most striking is the way in which she repeatedly positions herself as being an 'atypical MEP.' Here we see one such occasion.

> I figure here the most common – ah civil – job – for an MEP is er to be a lawyer. me myself *I'm far from that* the job I had doesn't even *exist* outside *Scandinavia*. so: it's a sort of a social teacher – so so I'm/I'm very in/an/a very special bird in this er: Interviewer mhm mhm so now you don't feel like you – fit into sort of a *typical* MEP er ME *no. no: no: I'm not. I'm left I'm a woman I'm Swedish* and I'm also everything – /everything's wrong (laughs).

In this example, the MEP contrasts herself with what she considers to be a typical profile for an MEP (lawyer by profession), emphasizing the degree to which she feels different (I'm far from that … I'm a very special bird … everything is 'wrong'). She also points out many of the identities that she associates with and that she perceives as marking her as different (social teacher, left, female, Swedish). This MEP is very much concerned with her self-presentation as being different, different than other female MEPs and also male MEPs. Moreover, she explains her success as a female MEP by being exotic and narrates different strategies which she applies in 'doing politics and gender.'

Even such short examples illustrate the diversity and complexity of gender roles and make clear why an interdisciplinary, qualitative, and context-sensitive approach is necessary to access the whole domain of 'gender and language.' To be able to make more general observations, however, much more cross-cultural comparable research is urgently needed.

Abstract

This article reviews factors that contribute to the gender gap in life expectancy, focusing on the leading cause of death, heart disease. A brief summary of gender differences in biological factors is followed by a presentation of behavioral and psychosocial contributions to women's greater longevity, and implications for prevention and treatment are discussed.

Gender Gap in Life Expectancy

Considerable gains in life expectancy have been observed for both sexes during the past decades. However, men still die about 5 years earlier than women (Murphy et al., 2013). This gender gap in life expectancy is largest when measured at birth, but shrinks with age. For example, if a man lives to 75 years of age in 2010, his life expectancy is only 1.9 years shorter than that of a woman's of the same age (Murphy et al., 2013). This shrinking gender gap with age is because men are more likely to die at younger ages than women. In the United States, the 15 leading causes of death in 2010 were (1) heart disease, (2) cancer, (3) chronic lower respiratory diseases, (4) stroke, (5) accidents (unintentional injuries), (6) Alzheimer's disease, (7) diabetes mellitus, (8) kidney disease, (9) influenza and pneumonia, (10) suicide, (11) septicemia, (12) chronic liver disease and cirrhosis, (13) hypertension, (14) Parkinson's disease, and (15) pneumonitis (inflammation of the lung). These 15 causes of mortality accounted for 80.4% of all deaths in 2010 (Murphy et al., 2013).

Almost all of these 15 leading causes of death show men to be at a greater risk than women. That is, the male-to-female mortality ratios (i.e., male age-adjusted death rate divided by the female age-adjusted death rate) ranged from 4.0 for suicide to 1.2 for septicemia. For heart disease, the major cause of death, the ratio was 1.5, and 1.4 for cancer, diabetes mellitus, kidney disease, and influenza/pneumonia. The only cause of death for which the ratio of male-to-female death rate was less than 1 was Alzheimer's disease (0.8), and women were as likely as men to die from stroke and hypertension (ratios = 1.0; Murphy et al., 2013). Several factors contribute to the gender gap in life expectancy. These can be grouped into three categories: biological, behavioral, and psychosocial (for more extensive coverage, see section on Gender in Whitfield et al., 2012).

Factors Contributing to the Gender Gap in Life Expectancy

Biological Factors

In her classic article, 'Why Do Women Live Longer Than Men?' Waldron concluded that "physiological differences have not been shown to make any substantial contribution to higher male death rates" (Waldron, 1976: p. 356). This conclusion has not changed much over the past decades (Gorman and Read, 2007; Waldron, 2005). Interestingly, international data on heart disease mortality from 46 communities in 24 countries have shown that male:female ratios vary widely, ranging from 10:1 in Iceland to 10:6 in Beijing, China (Jackson et al., 1997; also see Waldron, 2005). The fact that the differences between countries are larger than the difference between the sexes suggests that male anatomy is not destiny, at least in regard to heart disease. Additionally, the epidemic of cardiovascular diseases among young and middle-age Eastern European men has widened the gender gap in life expectancy over a very brief time span, which suggests that other than biological factors play a role in men's greater mortality risk (Weidner, 2010; Weidner et al., 2002; Weidner and Cain, 2003).

Behavioral Factors

Behavioral factors, such as smoking, excessive alcohol use, poor diet, and physical inactivity, are clearly involved in many of the major chronic diseases and causes of death worldwide (Lopez et al., 2006). For example, cigarette smoking has been linked to heart disease, lung cancer, chronic obstructive pulmonary disease, and pneumonia. Excessive alcohol consumption increases the risk for a number of diseases, foremost among them heart and liver disease. Excessive alcohol consumption, along with lack of seat belt use, also plays a major role in accidents and injuries in general. Other accidental deaths, such as homicide and suicide, often involve firearms. Overeating, unhealthy diets, and lack of exercise (associated with obesity) contribute to almost all chronic diseases, including diabetes, cancers, and strokes (Weidner, 2012).

An evaluation of lifestyle practices (i.e., smoking, physical inactivity, and unhealthy eating habits) in the INTERHEART study confirms their importance for myocardial infarction (MI), collectively accounting for more than 55% of the population attributable risk (PAR) in women and men (Anand et al., 2008), that is, the reduction in incidence that would be observed if the population were unexposed to these health-damaging lifestyle factors.

Generally, men are more likely to engage in health-damaging behaviors (e.g., smoking, unhealthy eating, excessive alcohol use) when compared to women. For example, women's diets have a lower ratio of saturated to polyunsaturated fat and higher vitamin C content than men's diets (Connor et al., 2002).

The only behavioral gender difference favoring men consistently appears to be physical activity. However, this finding may be due to the use of questionnaires designed for men, which focus on sports and neglect physical activities associated with housework (Barrett-Connor, 1997). Furthermore, stress may play a greater role for health-damaging behaviors among men than among women. For example, job strain appears to be associated with increases in health-damaging behaviors (e.g., cigarette smoking, excessive alcohol and coffee consumption, lack of exercise) among men, but not among women (Weidner et al., 1997; Weidner and Collins, 1993). Thus, considering the major behaviors involved in the leading causes of death, women appear to fare better than men.

Psychosocial Factors

Systematic assessment of psychosocial factors has not always been a part of large population studies of health outcomes. Most of what we know about psychosocial contributions to physical health conditions comes from studies of heart disease, the number one cause of death in the United States, accounting for 24.2% of total deaths in 2010 (Murphy et al., 2013). Psychosocial factors such as hostility/anger, depression/vital exhaustion, lack of social support, and work stress have prospectively been linked to premature mortality from all causes and heart disease mortality in both sexes (e.g., Holt-Lunstad et al., 2010; Kuper et al., 2002; Orth-Gomér et al., 2010; also see Depression, Pessimism, and Health in this section).

The importance of psychosocial factors for MI in both women and men has been most strongly illustrated by findings from the largest global study of MI, the INTERHEART study (Anand et al., 2008; Yusuf et al., 2004). This study compared over 15 152 cases with 14 820 sex- and age-matched controls in 52 countries on all continents. Most interestingly, in addition to eight commonly assessed risk factors of heart disease (e.g., hypertension, abnormal lipids, diabetes, smoking, exercise, moderate alcohol consumption), INTERHEART also included an assessment of eating a healthy diet and a psychosocial stress index. This index consisted of depression, stress at work or at home, financial stress, major life events, and low locus of control. Together, these risk factors were significantly associated with MI in both women and men and accounted for more than 90% of the PAR in both sexes. Interestingly, the lower burden of MI among women at younger ages (<60 years) was largely explained by their lower levels of risk factors: after statistical adjustment of these factors, the gender difference in the probability of MI before the age of 60 was reduced by 80% (Anand et al., 2008). The main contributors to the increased risk among the younger men were a high prevalence of lipid abnormalities and smoking, although men did appear to benefit from their greater (moderate) alcohol consumption. Examining gender differences in the PARs across all ages revealed several differences: higher PARs in women than in men were observed for hypertension, diabetes, abdominal obesity, physical inactivity, lack of moderate alcohol intake, and the psychosocial stress index. Men's PAR was significantly larger for smoking. In sum, findings from the INTERHEART study indicate that most premature MI is preventable and that interventions may benefit from targeting risk factors in a gender-specific fashion.

Gender-specific associations of personality attributes (hostility/mistrust), negative emotions (particularly depression), and social support/social isolation, as well as work stress, with health and well-being are discussed elsewhere (Barefoot et al., 1995; Leifheit-Limson et al., 2010; Orth-Gomér et al., 2010; Schwarzer and Rieckmann, 2002; Weidner and Spaderna, 2013). Generally, high levels of hostility/mistrust and depression and low levels of social support are related to harmful health outcomes in both sexes. Men consistently score higher on measures of hostility/mistrust and report less social support than women, which contributes to their increased health risk. Interestingly, both of these attributes are characteristics of the male ('macho') gender role, which has been linked to behavioral risk factors such as smoking, excessive alcohol consumption, and lack of seat belt use (Courtenay, 2009), as well as to decreased motivation to learn stress-management skills (Sieverding, 2002).

Additionally, women not only report more social support than men, but also have more sources of social support, thus decreasing their dependency on a single source. For example, studies of middle-aged people in Massachusetts found that men were more than twice as likely as women to name their spouse (or their partner) as their primary provider of social support (65.5 vs 26.4%). Furthermore, 24.2% of men (but only 6.1% of women) said this was their only source of support (New England Research Institutes, 1997). These data may, in part, explain why men's health is more seriously affected by partner loss through separation, divorce, or widowhood (Miller and Wortman, 2002).

In regard to negative emotions, gender differences appear to favor men. In most studies, women report more negative emotions such as depression than men (although this is not consistently found in populations where women and men have similar roles, such as college students; Nolen-Hoeksema and Girgus, 1994). Although women may report more depression, they may be coping more effectively than men. Generally, men are more likely to use avoidant-coping strategies, such as denial and distraction, whereas women are more likely to use vigilant-coping strategies, paying attention to the stressor and its psychological and somatic consequences (Weidner and Collins, 1993). Which style is more adaptive depends largely on the situation. Most stressful experiences consist of uncontrollable daily hassles, which are short-lived and typically of no great consequence. Here avoidant strategies would be more adaptive ("what I cannot control and what can't hurt me is best ignored"). Thus, men's strategies are likely to pay off for these types of events, contributing to their lesser experience (or report) of emotional discomfort or distress. But what if disaster hits? How do people cope with uncontrollable events requiring long-term adaptation, such as divorce, loss of a loved one, job loss, and sudden financial crisis and economic uncertainty? Here it may be women's greater vigilance that is more adaptive, such as preparing for the crisis, and seeking help and advice. Consistent with this reasoning are data from the Hungarian population that showed that women tended to accept their negative mood as a disorder to be treated, whereas

men were more likely to engage in self-destructive behavior, such as excessive alcohol consumption (Réthelyi et al., 2002).

Similarly, research on how people cope with disasters (e.g., hurricanes and tornadoes) has supported the notion of men's maladaptive coping: Increases in alcohol consumption and depression were related to personal disaster exposure among men, whereas no such direct relationship was evident among women (Solomon, 2002; Solomon et al., 1987). Furthermore, socioeconomic deprivation appears to be more closely related to depression in men than in women (Kopp et al., 2002). Thus, men's psychosocial risk factor profile appears to further enhance their risk for ill health.

Implications for Prevention and Treatment

Gender differences in behavioral and psychosocial lifestyle factors are likely contributors to the gender gap in several major causes of death. In regard to prevention, several large studies have now demonstrated significant health benefits to adopting a healthy lifestyle (e.g., a combination of a prudent diet, regular exercise, maintaining healthy body weight, and not smoking) for both women and men (Chiuve et al., 2006; King et al., 2007; Knoops et al., 2004). However, analyses of data from a community study of 15 708 middle-aged adults found that only 8.5% practiced healthy lifestyles (King et al., 2007). Although the percentage of women following healthy lifestyle practices was significantly larger than that of men, the low overall percentage is disconcerting. During a 4-year follow-up, 8.4% of participants newly adopted a healthy lifestyle (i.e., diets high in fruits and vegetables, regular exercise, maintaining a healthy body weight, and not smoking), and experienced a rather prompt benefit: mortality and cardiovascular disease risk were significantly reduced (40 and 35%, respectively) compared to participants with less healthy lifestyles (King et al., 2007). The authors also noted that men in general, African-Americans, and individuals with lower socioeconomic status were less likely to adopt a healthy lifestyle.

Although this study clearly demonstrates the benefits of adopting a healthy lifestyle, it also illustrates the problems associated with behavior change in primary prevention. Overall, efforts to reduce risk factors (via educational methods) in the general population have been disappointing. In their review of 39 trials, Ebrahim et al. (2006) conclude that "different approaches to behavior change are needed … the availability of healthier foods and better access to recreational and sporting facilities may have greater impact on dietary and exercise patterns … than health professional advice" (p. 2; also see Weidner and Kendel, 2010).

In contrast, attempts to change lifestyle behaviors in secondary and tertiary prevention trials (i.e., in people at high risk for disease and patients with the disease) have been more successful (Weidner and Kendel, 2010), but not without problems, especially in regard to overcoming barriers to participation. For example, the low utilization of cardiac rehabilitation by eligible patients has been attributed to several factors, including female gender (due to referral bias), medical insurance coverage, education, and ease of access to rehabilitation (Jackson et al., 2004).

In regard to psychosocial interventions, a meta-analysis of psychological treatment studies with heart disease patients concludes that psychological treatment is effective in reducing 2-year mortality by 27% (Linden et al., 2007). However, mortality was not reduced for women, for patients who perceived no reductions in stress, and for those whose treatment started right after the cardiac event (<2 months). Interestingly, the majority of women included in this meta-analysis were enrolled in the Enhancing Recovery in Coronary Heart Disease (ENRICHD) study. This study was a major multicenter, randomized clinical trial that tested the effects of a psychosocial intervention (aimed at decreasing depression and increasing social support) on reinfarction and mortality in 3000 post-MI patients at high psychosocial risk (i.e., depressed and/or socially isolated patients). Fifty percent of the patients were women. The study's results, with respect to the main outcome, were discouraging (Writing Committee for the ENRICHD Investigators, 2003). Considering that the intervention in ENRICHD started within 2 months after the cardiac event (a condition found to be ineffective in the later meta-analysis by Linden et al., 2007), the study's overall disappointing results may not be surprising. The unfortunate timing of the intervention may also explain the lack of benefit for women observed by Linden et al., as most of the women included in this meta-analysis were participants in ENRICHD.

Regardless of the reasons for the lack of benefit for women in Linden et al.'s meta-analysis, psychological treatments may have to be gender specific to yield beneficial outcomes for both sexes. The need for gender specific interventions may be most obvious for social support. For example, social support interventions seeking to elicit support from one's partner may be effective for men, who tend to see their spouse as their primary source of social support, but not for women, whose primary source of social support consists of friends and family members (New England Research Institutes, 1997). Consistent with this reasoning is the observation that single marital status and lack of spousal support predicted dropout from a comprehensive lifestyle change program among men with coronary artery disease (Koertge et al., 2003). Thus, soliciting social support from one's partner may be a promising intervention strategy for men but not for women, who could even experience exacerbated stress responses, as suggested by Kirschbaum et al.'s (1995) findings.

The need for gender-specific interventions also received support from a study conducted by Frasure-Smith and her colleagues. In their study aiming to reduce stress in male and female post-MI patients, significant gender differences were observed: direct advice about lifestyle changes seemed helpful for men, whereas listening to worries reduced stress in female patients (Cossette et al., 2001). Another investigation demonstrated a remarkable decrease in mortality among women with heart disease who were assigned to a stress reduction intervention specifically tailored to women (Orth-Gomér et al., 2009).

Finally, considering the fact that chronic diseases are influenced by a multitude of risk factors that are interrelated, implementing interventions aimed at the reduction of one factor alone may not be the most effective treatment strategy. As suggested by the findings from the INTERHEART study,

clinical, behavioral, and psychosocial risk factors contributed overwhelmingly to the risk of an initial acute MI. Most important, all identified risk factors are potentially modifiable. Thus, it would make sense to design interventions that target as many of these factors as possible. One intervention that targets multiple risk factors (diet, exercise, stress management, and social support) has been found to be beneficial for both women and men at various stages of heart disease and at different socioeconomic levels (for a review of this program of research, see Weidner and Kendel, 2010).

In sum, interventions targeting standard health risks (e.g., traditional medical risk factors such as hypertension, dyslipidemia), unhealthy behaviors (e.g., smoking, physical inactivity, unhealthy eating patterns), and psychosocial factors (e.g., social isolation, depression, maladaptive coping styles) are likely to benefit both women and men. However, given that there are many situational differences between men's and women's lives, a broader perspective on gender differences in health and well-being appears to be indicated (cf Courtenay, 2009). As a consequence, the design of gender-specific interventions may be required to yield effective outcomes.

Gender and Place

Daphne Spain, University of Virginia, Charlottesville, VA, USA

Abstract

The analysis of gender and place is interdisciplinary in that the field seeks to combine the spatial orientation of geographers, architects, and urban planners with the social focus of anthropologists, sociologists, and historians to understand the ways space and gender mutually reinforce each other. Places range from the geographic scale of the city or neighborhood to the building, and now to cyberspace. Gender identities include masculine, feminine, gay, lesbian, and an ambiguous 'third gender' of queer that recognizes gender identity as variable both historically and individually over the life course.

Introduction

'Gender and place' is a nuanced term for 'sex and space.' Both phrases refer to the ways in which gender or sex-role stereotypes are built into, and reinforced by, spatial arrangements. Take the adage that 'woman's place is in the home.' When ideology dictates that women should occupy only the domestic sphere, they seldom learn skills that would prepare them to enter offices or factories. Conversely, men who spend their days in corporate boardrooms or on the assembly line rarely are expected to excel at housework and childcare. Since single-use zoning laws typically separate homes from offices and factories, the association of gender with place is geographically inscribed on the city as well as attributed to individual buildings.

'Gender' represents socially constructed masculine and feminine (or some combination thereof) characteristics, while 'sex' refers to the biologically determined categories of male and female. One's sex is determined at conception, but one's gender identity develops over the life course and can fluctuate across a wide continuum of masculine and feminine characteristics. Girls who work on the family car in the garage and boys who cook meals in the kitchen are exhibiting gender characteristics incongruent with those expected of their sex; they are also occupying spaces inconsistent with gender expectations. A mismatch between space and gender is especially difficult for lesbian, gay, bisexual, and transgendered individuals to navigate (Doan, 2011).

Place is to space as gender is to sex: each pairing juxtaposes objective and subjective characteristics. Actual spaces can be designated with commonly understood boundaries of size or shape, but 'places' transcend simple attempts at measurement. Places are spaces imbued with significance. According to sociologist Gieryn (2000), space must meet three criteria to qualify as a place: A place is a unique geographical location, from a favorite chair to a region of the country; place has a physical, material form like streets, buildings, rocks, or trees; and place is invested with meaning and value. The space of a neigh borhood park may be a place to play for children, a place to sleep for the homeless, and a place to walk the dog for apartment dwellers. The park can be all of these places simultaneously or sequentially. The park may occupy a *space* the size of a city block, but it functions as a *place* for fun, shelter, or exercise depending on one's construction of its purposes. In short, space can be analyzed and measured; place is experienced. Cyberspace presents an enigma. It occupies an ambiguous position between the tangible characteristics of space and the subjective experience of place. Lacking physicality, chat rooms nevertheless create a sense of place, of being and belonging, for their participants.

Origins of the Field

The study of social structure and spatial structure emerged in the 1970s when geographer Harvey (1973) proposed that urban spaces and social relations are so intricately linked that a new language should be invented to capture the simultaneous occurrence of spatial form and social processes. During the 1970s, when feminist political activism was at its height, women were, quite literally, entering spaces previously open only to men. Colleges, factories, and offices became increasingly integrated by sex as women's place expanded beyond the home. Young women attending, and teaching at, universities during that era were among those who challenged the boundaries of traditional scholarship. The literal and symbolic collision of place and gender soon became a conscious subject of study in new interdisciplinary women's studies programs.

It is not surprising, then, that the first publications on gender and place were edited volumes generated from academic conferences about sex and space. Four of the most important volumes appeared almost simultaneously. *New Space for Women*, edited by sociologist Gerda Wekerle et al. (Westview Press, 1980) was a collection of papers presented at the 1976 United Nations Conference on Human Settlements that met in Vancouver. The editors organized a session addressing the role of women in the design and planning of urban settlements because they recognized that women's concerns about housing, transportation, health care, and the environment transcended categories of developed and developing nations. The next year, British anthropologist Shirley Ardener published *Women and Space: Ground Rules and Social Maps* (Croom Held London, 1981) as part of a series based on lectures sponsored by the Oxford University Women's Studies Committee. The edited volume included ethnographies of sex differences in the use of domestic and public spaces in the Andes, Greece, Iran, Russia, Nigeria, and South Africa.

In the United States, the Lincoln Institute of Land Policy sponsored a conference that resulted in the publication of *Building for Women* (Heath, 1981) edited by sociologist Suzanne Keller. It dealt with housing, community, and open space from a variety of academic disciplines; one of the chapters summarized the US Department of Housing and Urban Development's (HUD) Women and Mortgage Credit Project to facilitate women's ability to buy their own homes. HUD played a role in producing the fourth edited volume on women and space when it awarded a research grant to *SIGNS: Journal of Women in Culture* to commission essays for a special issue titled *Women and the American City*. The editor of *SIGNS*, Catherine Stimpson, subsequently published the volume (with Elsa Dixler, Martha Nelson, and Kathryn Yatrakis) through the University of Chicago Press in 1981. Contributors constituted the pantheon of researchers on women and space: Galen Cranz, Dolores Hayden, Jacqueline Leavitt, Susan Saegert, and Gerda Wekerle.

Donna Shalala, Secretary of Health and Human Services during President Clinton's administration, supported research on gender and place. Shalala was at HUD when the Mortgage Credit Project began and when *SIGNS* received funding for its special issue. As president of Hunter College, Shalala co-chaired the Ford Foundation–Hunter College Women and Housing Seminar with urban planning professor Eugenie Ladner Birch. Members of the seminar investigated the housing needs of single mothers, the elderly, and working women from the standpoint of design and affordability. The fruits of that pedagogical venture resulted in *The Unsheltered Woman: Women and Housing in the 1980s*, edited by Eugenie Ladner Birch (Center for Urban Policy Research, 1985), one of the first books to alert urban planners to the gendered nature of the housing market.

Urban planners Beth Moore Milroy and Caroline Andrews strengthened the tradition of edited volumes with *Life Spaces: Gender, Household, Employment* (UBC Press, 1988), a volume written entirely by Canadians about Canada. Milroy and Andrews introduced American audiences to geographer Suzanne Mackenzie, a founder of the field of feminist geography. Mackenzie, in turn, linked Canadian and American authors to British geographers Jo Foord, Sophie Bowlby, and Linda McDowell. *Life Spaces* departed from the model of previous edited volumes in one important respect: Wekerle's chapter on women's housing cooperatives included floor plans and photographs. Wekerle was one of the few social scientists to illustrate spatial concepts on the written page. During the first wave of scholarship, only Hayden and Birch (an architect and an urban planner, respectively) provided images of their topics. Today it seems obvious that books about space should include drawings and photographs, yet at the time authors rarely incorporated them.

Among pioneering scholars of gender and place, Dolores Hayden deserves special mention. Hayden's *Redesigning the American Dream: The Future of Housing, Work, and Family Life* (W.W. Norton, 1984) addressed the disparity between the massive single-family detached housing stock constructed after World War II and the decline of the nuclear family as the predominant household type. It opened debate among architects and planners about appropriate designs for new American families. Franck and Ahrentzen's edited volume on collective and single-parent housing, *New Households, New Housing* (Van Nostrand Reinhold, 1991) was a direct response to Hayden's challenge.

Differences in Scale: Cities, Neighborhoods, and Buildings

Cities, neighborhoods, and buildings reflect the gender assumptions of the era in which they are constructed. The post-World War II American metropolitan area took shape in the context of massive suburban expansion during a strong economy. Married-couple families were the norm, and middle-class white women could afford to stay home and raise the baby boom generation. The vast majority of architects, developers, and urban planners were men. Thus the suburbs were designed by men to appeal to mothers who seldom worked outside the home. Single-use zoning insured that residential neighborhoods were separated from commercial or industrial corridors, and public transportation was organized around men's commuting schedules. Only after divorce rates rose, fertility fell, and women entered the labor force did the gendered nature of cities reveal itself. Homes separated from employment and daycare opportunities, with little access to flexibly scheduled public transportation, became a liability for women.

Cities

Because almost all design and planning professionals were men at the turn of the twentieth century, the assumption is that women had little impact on the urban landscape. Yet there are historical precedents for both men and women building the city. In *Women and the City: Gender, Space, and Power in Boston, 1870–1940* (Oxford University Press, 2000), historian Sarah Deutsch argued that women reshaped the city's landscape to enhance their participation in public life. Working collectively through the Women's Educational and Industrial Union (WEIU), the Boston Women's Trade Union League, and the social settlement Denison House, women of diverse racial and social class backgrounds lobbied the municipal government to provide health clinics, vocational schools, and kindergartens. The WEIU located its headquarters at 264 Boylston Street, the city's legislative power corridor, to publicize women's accomplishments.

How Women Saved the City (Spain, University of Minnesota Press, 2001) explored similar themes. I examined four voluntary associations in which women played prominent roles at the turn of the twentieth century (The YWCA; The Salvation Army; the College Settlements Association; and the National Association of Colored Women) in Boston, Chicago, and New York to reveal the new spaces they created. Settlement houses, boarding homes, public baths, and institutions for unwed mothers were 'redemptive places' that saved the industrializing city from the onslaught of strangers streaming in from Europe and the rural South. While prestigious architects like Daniel Burnham were building monuments for the City Beautiful Movement, the less famous Vida Scudder was establishing settlement houses in New York and Boston to address problems in impoverished immigrant neighborhoods.

Cities and gender gained attention on the international front as well. In *A Women's Berlin: Building the Modern City* (University of Minnesota Press, 2008), architecture professor Despina Stratigakos examined the network of women's spaces in Wilhelmine Berlin from 1871 to 1918. The author took as her departure point a 1913 guide to the city written by and for women: 'What a Woman Must Know about Berlin.' The booklet introduced female residents and visitors to art schools that accepted women students; medical schools with gender-segregated anatomical theaters to avoid the risks of men and women viewing naked bodies together; a women's credit union; and women's clubhouses. The pamphlet exposed women to an entire range of places they could occupy outside the home.

In summer 2000, the International Women's University met at the University of Kassel (Germany) to discuss how the 'ideal' city would function and what it would look like. The conference attracted approximately 100 participants from different countries and cultures. They presented papers on the gendered aspects of transportation mobility, quality of life, public space, and urban design. This and other presentations were published in *City and Gender: International Discourse on Gender, Urbanism, and Architecture* (Terlinden, Leske and Budrich, 2003). A case study of a residential neighborhood in Haifa, Israel, for example, mapped women's interpretations of safe and unsafe places to walk. Their subjective assessments of the risks of crime affected how they navigated the city (Kallus, 2003; see also Fenster, 2005). Another book examining the way women and men experience urban space differently, *Cities and Gender* (Jarvis, Cloke, and Kantor, Routledge, 2009) illustrates the intersection of urban and gender studies in European, North American, and global south cities. Leslie Kern's *Sex and the Revitalized City* (UBC Press, 2010) applies a gendered lens to condominium development and urban citizenship in Toronto, Canada.

Neighborhoods

Studies at the neighborhood scale have produced a body of literature on gays' and lesbians' use of space. Manuel Castells' mapping of San Francisco's gay male culture was one of the first explorations into the relationship between homosexual subculture and space. Castells proposed that spatial concentration is fundamental to the development of gay identity. He argued that gay men are more likely to establish urban neighborhoods than lesbian women because men's tendency toward dominance extends to territorial aspirations, while lesbians' emphasis on relationships transcends space, making lesbians 'placeless' and more politically radical (Castells, 1983, p. 140; Castells and Murphy, 1982). Urban planners Sy Adler and Johanna Brenner (1992) challenged Castells' analysis, arguing that women's lower incomes, responsibility for children, and vulnerability to male violence had more to do with their location decisions than the bonds of lesbian relationships.

Gay men, and to some extent lesbian women, have played significant roles in the revitalization of American urban neighborhoods (Forsyth, 1997; Lauria and Knopp, 1985). As early as the 1920s, gay men led efforts to protect and restore New Orleans's French Quarter (Reed, 2012). Commercial areas catering to gays and lesbians, such as San Francisco's Market Street and Chicago's Halsted Street, display highly visible rainbow flags to attract clientele and, increasingly, tourists. Many cities now host Gay Pride parades. Even Walt Disney World, that bastion of family values, introduced Gay Days in 1991; by 2010 the event had expanded to all of Orlando and attracted more than 135 000 people. Gay and lesbian community centers, bookstores, and health clinics have become staples in many cities; gay and lesbian parades and festivals temporarily transform city streets. Being out in public often subjects gays and lesbians to harassment. Houston formed a community-based, police-affiliated Q-patrol to ensure that teens would not gather in key gay locations to cause trouble. Police departments in Chicago and San Diego recruited gay and lesbian officers. These efforts to make public spaces safer were initiated by queer activists (Forsyth, 2011). Making gays and lesbians welcome, in fact, has become a hallmark of Creative Cities (Florida, 2005).

Pressure is mounting to nominate prominent gay and lesbian sites as historic landmarks, like New York City's Stonewall Inn, where a police raid sparked the riot acknowledged as the catalyst for the gay rights movement (Dubrow, 1998). Such places have become easier to identify as gay and lesbian histories with a spatial focus have emerged. Chauncey (1994) has described how gay men appropriated public and private spaces to provide settings for the expression of gay culture in New York City between 1890 and 1940, while Kennedy and Davis (1993) have mapped the landscape of lesbian meeting places in Buffalo, New York, between the 1930s and 1960s. The National Trust for Historic Preservation lists many homes of prominent figures without including their sexual orientation in the narratives of place. Georgia O'Keeffe's property in Abiquiu, New Mexico; Philip Johnson's Glass House in New Canaan, Connecticut; and Willa Cather's childhood home in Red Cloud, Nebraska, are a few of the places gay and lesbian preservationists would like to see recognized (Dubrow, 2011).

Buildings

Homes, schools, offices, factories, and civic monuments are gendered places in at least three ways. One is in the principles underlying 'good' design; one is in the sex of the person who designs them; and another is in the connotations the building evokes.

Gendered principles of design originated with the Roman builder Vitruvius, who wrote *De Architectura* (*The 10 Books of Architecture)* around 25 BC. In Book III Vitruvius identified the male figure as the principal source of geometry for Classical architecture. Leonardo da Vinci's late fifteenth-century drawing, based on these ideal human proportions, became known as 'The Vitruvian Man.' It depicted a nude male figure in two superimposed positions, arms and legs outstretched, inscribed within a circle and a square. American adaptations of Vitruvian ideals are evident in Thomas Jefferson's neo-classical designs for Monticello and the University of Virginia, and in Daniel Burnhams City Beautiful monuments of the late nineteenth century. The highly influential mid-twentieth century French architect Le Corbusier worshipped geometric form to the extreme. American public housing residents have Corbusier to thank for the international style inflicted on them during

the 1950s. Would the history of architecture be different if there had been a 'Vitruvian Woman'? Impossible to know, of course, but many artists have proposed their female version of the famous diagram; a web search produces nearly 9000 images of 'Vitruvian Woman.'

Whether women and men design differently is a matter of debate. It was a moot point until recently, since for most of history architects have been men. In the United States, the 75 female architects registered by the American Institute of Architects and practicing in the first half of the twentieth century remain largely unrecognized. The exception may be Julia Morgan, who designed San Simeon castle for William Randolph Hearst during the Depression (Allaback, 2008). The question about gender differences in design has arisen as more women have joined the profession. Progress has been slow, however, in 2011 only 21% of practitioners were women (U.S. Bureau of Labor Statistics, 2012). Several of these, like Denise Scott Brown, are in husband–wife partnerships.

Does this small minority of women introduce feminine features into their buildings that their male colleagues omit? Do they conduct business differently from men? The stereotypes are that women tend to work in small firms, specialize in residential or human service projects, listen carefully to clients, and collaborate with their colleagues. In contrast, men tend to work in and for the corporate world, creating prize-winning signature buildings that express their rather sizable egos. Frank Gehry and Rem Koolhaas come to mind.

The most famous female architect today, Zaha Hadid, also has a distinctive style (and an ego to match any man's), as did Eileen Gray and Lucy Hillebrand, two other pioneering women architects. But their work has little in common, each exhibiting an 'exceptional peculiarity' that defies gender stereotyping (Dorhofer, 2003). The same could be said of Andrea Leers and Jane Weinzapfel, principals of Boston's Leers Weinzapfel, and Carol Wedge, president of Boston's Shepley Bullfinch (Landsmark et al.,, 2010). Chicago architect Jeanne Gang, however, has imbued her 82-storey apartment building, Aqua, with feminine touches in the very heart of the city that invented the skyscraper. Architectural critic Paul Goldberger (2010) credits Gang with figuring out how to give "brawny materials" "soft, silky lines, like draped fabric." She achieved the architectural and engineering feat by wrapping a rectangular glass slab with curving concrete balconies, turning the façade into an 'undulating landscape' that shades apartments from summer sun and dissipates high winds. Goldberger attributes Gang's success to her attempts to see the building from the perspective of its users rather than through a strict ideological lens of modernism.

Buildings also invite associations with masculine and feminine characteristics. Grand civic monuments are meant to convey the power of the state, represented by the men who traditionally occupied their corridors. Less imposing 'human-scale' buildings, on the other hand, are typically more comfortable places for women. Then there is the skyscraper. Noting the phallic connotation of skyscrapers is a cheap shot, since they are also the most cost-effective way to create commercial and residential space on expensive urban land. But business tycoon Donald Trump's insistence that his buildings are the tallest is a silly reminder of the analogy.

Some buildings designed specifically for women or men lack any exterior evidence of their identity. Architect Lupkin (2010) argues that the typical nineteenth-century Main Street YMCA, a brick building standing only three or four stories tall, was instrumental in redefining masculinity at the turn of the twentieth century. The YMCA's leisure spaces, its dorms, and its educational facilities were key elements in a spatially segmented system of class, race, and gender that helped define a 'culture of corporate capitalism' in the modern city (p. xvi). The YWCA, constructed specifically for single women, was equally as innocuous as the YMCA, and equally dedicated to defining proper gendered behavior in the industrializing city (Mjagkij and Spratt, 1997). Like women's and men's clubs, YWCAs and YMCAs were sites of gender formation for Americans entering the modern age.

A significant British book addressing differences in scale was Moore's *Space, Text, and Gender: An Anthropological Study of the Marakwet of Kenya* (Cambridge University Press, 1986). Moore drew on the theories of Foucault (1972) to analyze household space as a 'cultural text' representing gender relations in Marakwet society. The study placed the Marakwet in their geographic context with a map of Kenya and a diagram of their Sibou village, and in their building context with photographs of their dwellings. Moore's work progressed from a base of great geographical expanse to the smaller scale of the building. *Space, Text, and Gender* marked another important milestone. It was one of the first full-length ethnographies devoted to the topic of gender and place. Although edited volumes would still fill a niche, the field acquired stronger intellectual credentials with the publication of books posing theoretical arguments. My own work sought to extend that tradition. *Gendered Spaces* (Spain, University of North Carolina Press, 1992) was a cross-cultural and historical study proposing that women's status is lower in societies in which men and women are separated spatially in homes, schools, and workplaces because spatial segregation prevents women from gaining the 'masculine' knowledge most highly valued by society.

The Future of Gender and Place

The original scholarship on gender and place equated gender with women, as illustrated by titles like *New Space for Women* and *Women and the American City*. Two developments since the 1980s have enlarged the focus of research. First, contemporary work addresses men and masculinities in addition to women. Second, just as current work has broadened the concept of gender, future work promises to extend concept of place into cyberspace.

Sociologist Michael Kimmel was among the first scholars to introduce males into the conversation about gender. From *Manhood in America: A Cultural History* (Free Press, 1996) to *Guyland: The Perilous World Where Boys Become Men* (Harper, 2008), Kimmel has insisted that discussions of gender are incomplete as long as the focus is on women only. In *Guyland* he argues that it takes time for boys to learn how to become adults, and that the process is facilitated by "a place, or rather a bunch of places where guys gather to be guys with each other" safe from the scrutiny of parents or girlfriends (p. 4). Sports bars, TV or game rooms (aka 'man-caves'), dorms, and

fraternity houses are all part of 'Guyland,' at least for the middle class. Lower-income adolescents might learn how to be men in gangs that defend their turf. Like the nineteenth-century YMCA, these contemporary places are sites where youth can try out new identities in a safe space.

In 1998 Kimmel founded the journal *Men and Masculinities*. The first issue published articles titled "Masculinities and globalization" and "What is problematic about masculinities?" The peer-reviewed interdisciplinary journal was established to 'explore the evolving roles and perceptions of men across society' with empirical and theoretical scholarship from the perspectives of feminism, queer theory, and multiculturalism. A 2010 special issue was devoted to men in women's jobs, specifically men performing domestic service (Sarti and Scrinzi, 2010). It included articles on the masculine aspects of international migration and the globalization of care, topics typically covered from the women's standpoint (see Ehrenreich and Hochschild, 2002). The June 2013 volume included a review of the journalist Joel Stein's book *Man Made: A Stupid Quest for Masculinity* (Grand Central, 2012), about his search for ways to act manly when he became the father of a son. One might think of it as '*Guyland* lite' for adults. Then there's the *Journal of Men, Masculinities, and Spirituality*. This list of sources with masculinity in the title illustrates that after more than three decades of equating gender with women, the field of gender studies has become more inclusive. (Or, as some feminists might complain, men have found yet another way to become the center of attention.)

What does the future hold for the study of gender and place? It will definitely involve cyberspace, as the literature already suggests (Boyer, 1999; Light, 1995). For its female participants, the *World of Warcraft (WoW)*, a massive multiplayer online role-playing game, is a space connected to the real world; women take their off-line gender identities and social contexts with them when they go into the virtual world (Eklund, 2011). As the matrix of cyberspace supplements the grid of the city, women may experience the environment differently from men. Possibilities for gender ambiguities abound on the Internet in 'chat rooms' that allow more anonymity than face-to-face interactions. The digital landscape has the potential to change women's status, if it changes the way knowledge is disseminated. The gendered spaces that once limited women's access to knowledge, and thus power, may dissolve. For example, Muslim women living in the Western world use the Internet as a discursive space in 'fatwa sites,' where they raise questions about which rules govern gender behavior in a non-Muslim culture. Lacking a neighborhood mosque, women can consult an online imam to clarify Sharia law regarding dress code, rights to abortion, and mixing with the opposite sex. These fatwa sites have the potential to change Muslim family law (Ali, 2010).

Conclusion

The study of 'Gender and place' emerged during the 1980s to identify ways in which gender stereotypes and spatial arrangements reinforce each other. Over its brief history, the topic has become increasingly differentiated with respect to definitions of both place and gender. Cities, neighborhoods, buildings, and even cyberspace are spaces that become 'places' to the people who produce and use them. 'Gender' extends beyond the dichotomy of masculine and feminine to encompass lesbians, gays, bisexual, transgendered, and queer identities.

Gender and Social Research

Abstract

Globally, in the past two decades, there has been a remarkable expansion in social research on gender. But gaps and obstacles remain, including contentious issues with regard to ethics of research. This article provides a general description of the current situation of social research on gender – particularly the participation of women researchers, a discussion of methodological developments in gender research, moral and ethical issues on scientific validity, representation, and exclusion of women in clinical research.

Introduction

Indicative of the expansion in social research on gender since the 1990s is the proliferation of centers and programs for gender studies in academia, development agencies, and government and nongovernment organizations. For example, there are now more than 900 gender/women/feminist studies centers worldwide that have websites (Women's Studies Programs, Departments, & Research Centers). Many of these focus on women studies.

Public and private international funding institutions, government and semi-government bodies as well as the UN have set up gender programs aimed to encourage and support research on gender and women.

Gender studies tend to be interdisciplinary where researchers from diverse disciplines and fields bring their expertise together. Additionally, intersectoral and international collaboration among academic, civil society, and government researchers is becoming a trend.

Women Researchers

There have been improvements in the participation of women in research, but significant gaps remain. In most OECD member-countries (OECD), for example, the percentage of women among the total number of researchers in science and technology (S&T) has increased between 2004 and 2009, but no country registered a parity. The lowest participation is in Japan, at 13.6%, followed by Korea at 15.8%.

Globally, it is in S&T where the gap is alarming (WISAT). The situation is far better in Latin America and the Caribbean where women researchers are 46% of all the S&T researchers (ECLAC, 2013). However, senior posts are dominated by men. One reason is women scientists have to choose between career and motherhood. *The history of women scientists has been one of moving from exclusion to segregation* (ECLAC Report of October 2013 quoted in Elena Hurtado, 27 November 2013).

In psychology, the social sciences, and life sciences, there has been an upsurge in the number of women who earned doctoral degrees (Fox, 2004). The rapid expansion in the ranks of women in academia prompted Long to say that women have moved from *scarcity to visibility* (quoted in Ginther and Kahn, 2012: p. 2). But it is still an uphill climb for women. Only 30% of tenured faculty of US academics are women. The gender tenure gap is largest in economics and the social sciences. Worldwide, women constitute on average only 29% of all researchers (UNESCO, 2011, report cited in UN ECLAC report, October 2013). Again, having children is the most influential factor that causes the gender gap (Ginther and Kahn, 2012).

A researcher's productivity and quality of work in international academic culture are weighed in terms of publications, especially the citation counts for the author and the publication which have "historically been viewed as a relatively objective measure of the quality and impact of research" (Maliniak et al., 2013: 1). Using a gender lens, Maliniak et al. did the first study of its kind in examining patterns in citation and peer reviewed publications in international relations from 1980 to 2007. After controlling for a large number of variables, they found that women authors are *systematically less cited than men*. The authors think that this is because women tend to cite themselves less than men, and men tend to cite men authors more than women authors.

This is corroborated in a global review of published authors in international relations by Lariviere et al. (2013) where they found persistent gender gaps. In countries with the highest number of published researchers, women as the main authors were less cited than men in the same position. The gender disparity is being sustained by a system of using citations in the evaluation of researchers, and much more so for those in the social sciences, where there are more women authors than in the other disciplines.

The iniquitous system not only works against women but also against researchers in less developed economies. "Research evaluation that use quantitative measurements such as bibliometrics pose a severe limitation for countries where only a few researchers get published in international peer reviewed journals" (UNESCO, 2010: p. 5).

Shifts in Usage of 'Gender'

The term 'gender' is now commonly used including in the mass media. But there have been shifts in its usage such as exchanging sex and gender, exemplified in the US Food and Drug Administration's (FDA) use of gender (Miller, 2001). It is

now common to see gender instead of sex in survey questionnaires (i.e., for data on respondent's personal profile, similar to age). Used in the FDA and survey contexts, gender is used when the data being collected is on the biological characteristic, male or female. The socio-political meaning of gender is absent.

This is not the way feminists who brought the concept to public consciousness and political discourse mean in their use of gender. Gender is a social construct that attributes particular characteristics, abilities, roles, privileges, and entitlements to males and females. This attribution is manifested in every facet of social, economic, and political life.

As an analytic concept, it is the lens with which power, its location, and its distribution in various levels and dimensions of social life are examined including in relations in the research setting (Smith, 1987). But gender has become a "taken-for-granted buzzword" (Cornwall quoted in Sabea, 2008: p. 16) – the "workhorse concept" (Olesen, 2011: p. 135). The loose usage of gender for sex could erode the political import of the terminology. "The question remains how to refuse being incorporated, co-opted, or rendered superfluous and nonthreatening" (Sabea, 2008: p. 22).

Focus on Women

There have been criticisms on the focus on women and the marginalization of men in gender work (Proudlock, n.d.). An extreme example not in research but in medical practice is the controversial prohibition issued by the American Board of Obstetrics and Gynecology in September this year for members against treatment of men. Larry Gilstrap, a high official of the Board said: "if you want to voluntarily be known as a specialist in obstetrics and gynecology, it is restricted to taking care of women … There are plenty of physicians out there to take care of men." (Grady, Denise, 23 December 2013. Gynecology's gender question. The New York Times. From: http://www.nytimes.com/2013/12/24/health/gynecologys-gender-question.html?smid=tw-nytimes&_r=1& (accessed 23.12.13.)). A forceful argument was made by bell hooks (1984), considered a major thinker for radical feminism, that while men benefit from patriarchy more than women, it also oppresses them. "… I believe that if they (men) knew more about feminism they would no longer fear it, for they would find in feminist movement the hope of their own release from the bondage of patriarchy" (p. 1X).

An experience of a women's rights group in Asia shows that excluding men resulted in violence against the women who participated in the projects perpetrated by dominant males in the family (Estandarte and Alvarez Castillo, 1999).

Women rather than men are the central focus in gender research for three main reasons: (1) women bear the greater burden of oppression and inequality (Lengermann and Niebrugg-Brantley, 2003); (2) women's real life situation has been largely ignored in mainstream research (Lather, 1988); and (3) men and their life situation cannot represent women and their life situation (Mies, 1983).

Gender Bias in Research

Gender bias in research is documented in the literature (Ritchie, 2009). Common examples of gender bias in research are exclusion of women of reproductive age in clinical trials (discrimination – this will be discussed later in this article), using the household as unit of poverty measurement in economic research (Pogge and Rippin, 2013) (gender blindness), and women-only reproductive health studies (stereotyping).

Although not as pervasive and obvious as before, gender bias is still present, unrecognized, in various forms and degrees (Ritchie, 2009). Masculine characteristics are privileged over feminine characteristics. Contemporary social science research inherited this fundamental bias. This is why knowledge and knowing in the social sciences for a long time has been male oriented (Reinharz, 1992; cf Americas, Sociocultural Overviews: Caribbean).

There can be gender bias in every stage and process of social research, from the determination of the research purpose to the dissemination of research findings. It can be found in relationships among researchers in a project or in policies of funding institutions. Even in research ethics guidelines, in the ethics review system, there could be gender bias.

Research Gaps

Very important and wide-ranging findings about gender are now available, many of which have informed international and local policies and programs. There is so much that is now known and understood about the nature, dynamics, and consequences of, for example, gender bias, discrimination, and inequity, on women, families, communities, and societies in various contexts and historical periods. This being so, it is at this juncture that effects of the reforms on structures or systems, particularly on power shifts in socio-political life, should be examined. For example, there is no sufficient knowledge of the impact of policy reforms on the real life situation of women and girls. Susan Franceschet (2003) asked whether or not 'state feminism' has been good for women. There are questions whether invited participation (women invited by the state) is better than demanded participation (women's participation is fruit of their insistence) in forging ahead the struggle for justice for women (Murthy et al., 2005). On the other hand, there is scant attention to the impact on research on gender of the behavior and changing agenda of donors. Deep and comprehensive analysis beyond the statistical data on performance vis-à-vis the UN gender gap indicators and the Millineum Development Goals is needed.

With this background, among the issues that have not been given attention relative to the other issues are as follows:

- effects of global and state reforms on women's situations in various levels and contexts;
- structural or systemic effects of increase in the number of women and girls in education, in the domestic and migrant labor force;
- the effects of globalization of neoliberal agendas on women and girls;

- the interconnections of the women's rights movements and the larger human rights movements;
- the specific forms and character of oppression due to the intersection of social class, ethnicity or race, and gender;
- political power of, for, and by women; and
- power, dynamics, and effects of donors on research and the women's struggle.

Paradigm Shift, Methodological Revolution

There have been a paradigmatic shifting (Denzin and Lincoln, 2011) and a methodological revolution (Fonnow and Cook, 1991) in the social sciences since the 1970s. Perspectives long held to be universally correct about the nature of knowledge and the best ways of producing it were challenged while radically different approaches and innovative research methodologies are put forward (cf Feminism in Anthropology; Objectivity of Research: Ethical Aspects).

The contributions of feminist scholars are central in the paradigmatic turn and methodological revolution (Ramazanoglu, 1992) (cf Feminism in Anthropology). Feminist perspectives and reflections on their research experience constitute a distinct body of knowledge in the social sciences today.

The twentieth century women's rights movements provided impetus for contemporary feminist epistemology and methodology. Ann Oakley (1974), for example, whose sociological classic, Housewife said in an interview that the emerging feminist movement in the late 1960s was a major influence in her choice of the subject matter, housework.

Feminist Methodology

Feminist perspectives on the nature of knowledge and methods for knowing have influenced researchers worldwide. The methodology evolves as researchers try to find ways for knowing, describing, and making sense of the complexities and realities in women's lives usually hidden or unrecognized (Mama, 2013).

Feminist research is usually qualitative. However, there is diversity and contentiousness in feminist qualitative research (Olesen in Denzin and Lincoln, 2011). While Maynard (1994) thinks there is a distinct feminist methodology, Hammersley (1992) argues that feminists did not invent feminist methods. The commonly used data collection techniques are unstructured interviews, story telling, narratives, role play, observation, and conversation. While some of these are not invented by feminists and not all who use them are feminists, what distinguishes feminist methodology is their use with sensitivity to context, to the power relation between the researcher and researched, and with reflexivity.

Qualitative instead of quantitative methods are preferred because these are less alienating and researcher controlled or directed. Many critical researchers including feminists use both qualitative and quantitative methods because these are seen as not mutually exclusive (Jayaratne, 1983). What is important is attention to context; social conditions and hidden structures of social relations are surfaced and critically examined (Neuman, 1996). These promote rapport and empathy and provide women space and context to talk, and for both the researcher and the women to negotiate the meanings of emerging data. Because researchers must be sensitive to the context of the women, the research plan is tentative, not fully mapped out, and structured. "Feminist research in Africa … have nearly always been improvised and adapted for local usage, often in ways that are not fully conscious, and which often go unreported … a skilled feminist researcher gathering information in a community she is familiar with will be nuanced and adapted by her knowledge of the cultural context, its particular modes of orality and locally specific speech codes inflected by gender, ethnicity, class and age," (Mama, 2013).

There are those who are skeptical about the scientific rigor of feminist research (Hammersley, 1992; Hussain and Asad, 2012). This and other contentious points on representation/voice and the exclusion of women in clinical trials are discussed as ethical/moral contentions in the following section.

Scientific Soundness and Ethics

The scientific quality of feminist research has been questioned on three grounds: (1) lack of methodology or unstructured methodology; (2) highly subjective process of data collection and interpretation (cf Objectivity of Research: Ethical Aspects); and (3) blurring of the political and scientific boundaries.

If feminist research is unscientific, then it is also unethical based on three major guidelines for ethics in research being used by ethics review committees for health research (including social research in health) worldwide: the Declaration of Helsinki (DoH; World Medical Assembly, 2013), Council for International Organizations of Medical Sciences (CIOMS) Guidelines (2002 International Guidelines for Biomedical Research Involving Human Subjects), and the UNESCO Ethical Guidelines for International Comparative Social Science Research (in the Framework of MOST (Management of Social Transformations) Program of UNESCO, 1994–2003). It may be noted that there is no international ethical guideline for social science research that is comparable to the influence of DoH and CIOMS in biomedical research.

What is the 'generally accepted standard of scientific research' that is unbiased and whose findings are ' generalizable'? It is the positivist standard of scientific research. The major guidelines have an implicit bias for positivist, quantitative research methods. *Ipso facto*, these are biased against feminist, openly political, qualitative research that are not attuned to making generalizations but to theory building.

Feminist research has made the clearest and most comprehensive critique of positivist notions of scientific objectivity. For example, Bennett said, "Designing research methodologies capable of addressing the questions which compel us constitutes a politics in its own right, demanding a re-evaluation of received approaches and sophisticated reflection on the intersections of theory and practice" (2008: p. 1).

Feminist research rejects positivism's reliance on highly standardized and formalized techniques of quantitative measurements because these alienate the very vulnerable, powerless, and unheard; are insensitive to context; cannot

uncover hidden inequities; and gloss over specific realities and experiences (Harding, 1986; Maynard, 1994), yet they are used to make generalizations about social life (Scheyvens and Leslie, 2000; Finch, 1984).

It rejects positivism's norm of objectivity (Maguire, 1987) defined as value free and therefore bias free because of the following:

- It is impossible to remove values/bias in the researcher as an embodied, situated social being.
- Bias is masked/hidden by quantitative techniques that create a semblance of absence of the researcher's subject position in the study (Meis, 1983).

Conversely, qualitative methods "can be highly effective for creating a feeling for the whole, for grasping subtle shades of meaning, for pulling together divergent information, and for switching perspectives. It is not an excuse for doing poor quality research, and it has its own discipline and rigor" (Neuman, 1996: 319).

There is ideology in both positivist and feminist methods. In feminist research, the method is simultaneously several things at the same time: a way of collecting data; a language; and a message about the researcher's values regarding the place of the women in the study. The women are viewed as experts closely involved in the process of constructing knowledge about their own lives (Craige, 1992).

In positivism, method is a tool to get data. People are treated simply as data sources and the researcher due to his expertise is privileged to interpret and use the data.

In other words, there is bias in both positivist and feminist research – the questions are: what is the bias, for whom it is, and why this bias? Lather (1986) observed that "research which is openly valued based is neither more nor less ideological than is mainstream positivist research" (64) (cf Objectivity of Research: Ethical Aspects).

Feminist Politics and Scientific Rigor

This is the period of post-positivism (Guba and Lincoln, 1981). No researcher speaks anymore of doing research for knowledge' sake or that they are value free (Hesse, 1980). There is a disconnect between this observation and the major ethics guidelines identified earlier, which stipulate that research must be unbiased and should follow mainstream scientific methods. Ann Oakley (1992) describes the negative reception from funders and scientific review bodies because of her research methods. Ackerly and True (2010) observe that review committees push hard on qualitative researches but do not provide enough guidance on ethical problems for qualitative researchers. On the other hand, critical researchers openly define their political stand with regard to the research (Mies, 1983).

Commitment to the interest of people being studied is a matter of justice. "Siding with the people one researches inevitably means an emotional as well as intellectual commitment to promoting their interests. How else can one justify having taken from them the very private information which many have given so readily?" (Finch, 1984: p. 178).

The point then is not that researcher bias makes poor research. The point is to ensure that bias does not stand in the way of credible, trustworthy data. "The issue is not theoretical vigor versus methodological rigor. The vitality of postpositivist research programs necessitates the development of credibility checks that can be built into the design of openly ideological (and phenomenologically based) research. Both our theory and our empirical work will be the better for the increased attention to the trustworthiness of our data" (Lather, 1986: p. 77). Trustworthiness rather than validity is central to the feminist concept of scientific rigor. Lather (1986) discusses different validity tests in feminist research.

Validity in Feminist Research

Commitment to justice for women is not enough. "My concern is that efforts to produce social knowledge that is helpful in the struggle for a more equitable world pursue rigor as well as relevance … we must formulate self-corrective techniques that will check the credibility of our data and minimize the distorting effect of personal bias upon the logic of evidence" (Lather, 1986: pp. 67–68).

Self-corrective methods have been evolved over time. One is transparency with political standpoint and research background.

Another is detailed description in the research report of the entire research process, from inception to data collection, interpretation, validation, dissemination, and use of findings (Oakley, 1992).

A third method is reflexivity. Derived from Freirean philosophy, reflexivity in research is a complex and deeply personal, sometimes painful process of sensitizing oneself. The researcher reflects on her own consciousness, biases, where she is coming from, and how all these affect her relationship with the people she is studying as well as the data that she is collecting and analyzing. The practice of reflexivity and the perspectives underlying it are among the most distinctive contributions of feminist research in epistemology and methodology.

Fourth method is triangulation. There are three procedures: triangulation by method, by data source, and by researcher (Patton, 2001). More than one method is used in collecting similar sets of data from different data sources by more than one researcher. In cases where data collection is done by only one researcher, triangulation by researcher involves the reinterpretation of the data set by a different researcher. There are, however, variations in triangulation by researcher – randomly chosen datasets, instead of the entire data, may be interpreted by more than one researcher.

Fifth method is member check (Patton, 2001). In this method, interpretation or findings are brought back to research participants for confirmation. Some researchers, to protect confidentiality and participant's anonymity, provide feedback of findings to individual participants in separate sessions.

Integrity and Validity in Research

In the DoH and CIOMS guidelines, researcher integrity is considered in terms of absence of conflict of interest, technical competence, and compliance with intellectual property

regulations. In qualitative research, researcher integrity is a central issue (Neuman, 1996). "We set stringent statistical criteria not because logically they are crucial for establishing the truth of a theory but because our intellectual community is socially distrustful of the honesty of investigators" (Collins, 1984 quoted in Neuman: 321). Where feminist research uses self-correcting procedures, "to some degree a quantitative researcher substitutes explicit descriptions of standard techniques and statistics for trust" (Neuman, 1996: p. 321).

In feminist research, there is an overlap of politics, methodological rigor, and ethics. Ethics could be an inaccurate term to capture the depth and complexity of dilemmas experienced by feminist researchers, especially those who study highly vulnerable groups such as victims of violence, homeless, and indigenous women. In her reflexive writing about her research experience, Finch (1984) observes, "my commitments as a feminist raised moral questions for my work as a sociologist" (p. 176). Her dilemmas were moral and she finds "sanitized intellectual discussion of ethics irrelevant" (p. 178).

Politics of Representation

The second moral dilemma is the question of representation or voice in feminist research. Postmodern and other feminist scholars, especially women of color and indigenous women, raise the issue of universalizing the western, white middle class women's views about women and their life realities for the rest of the world (Collins, 2000). They identify fundamental differences in the issues of women contextualized in specific intersections of race, culture, ethnicity, class, history, and the prevailing political economy. It is not fair to impose categories born from specific contexts on other contexts (Fontes, 2004).

The criticisms affected many researchers not only in the west but also in other countries doing cross-cultural studies. They question themselves if indeed what they are doing will be useful to the women in these cultures (Scheyvens and Leslie, 2000). For example, one has to grapple with the dilemma: should it be simply a description without making an analytic judgment of the oppression? Yet to describe is to interpret, and interpretation involves the deployment of a conceptual frame. The moral dilemma is, whether it is fair to study women in other cultures and describe to the world their realities (cf Scheyven and Leslie, 2000).

The dilemma is sharp with researchers whose purpose is not only to know but to use what they have known to empower women. For example, "when women themselves do not see gender inequality as a material issue, or where women themselves do not see the need for their active participation in political activities, should researchers or external actors insist on taking up the issues?" (Alvarez Castillo and Cook Lucas, 2010: p. 34).

Others think that asking the marginalized, the unheard about their situation, listening to their stories, and sharing these with the rest of the world could contribute to their empowerment. These could affirm their self worth in knowing that they can contribute to knowledge. By thinking about hitherto unspoken subjects or unasked questions, consciousness change can take place (Acker et al., 1991).

There are two kinds of initial reaction to the criticisms: many western researchers inhibited themselves from doing cross-cultural studies; others took a relativist stance (Scheyven and Leslie, 2000; cf Cultural Relativism, Anthropology of). Relativism belongs to a theoretical school that rejects the notion of absoluteness of truth or values like goodness or justice. What is true or good is relative. At the same time, there are those who, despite their self doubt over their relevance, experience affirmation from women in other cultures of the usefulness of what they are doing. Reinhraz (1992) thinks that women's concerns in the west are universal concerns of women, but they should know and understand women and their specific contexts in other countries. It is crucial to recognize the presence of multiple perspectives and to be sensitive to situations where these perspectives come (Lugones, 1987).

The researcher must acknowledge that she made choices in constructing her representations of other women (Haraway, 1988; cf Research Ethics, Cross Cultural Dimensions of); that her social situation affects such representations (Harding, 2004).

Women's Exclusion in Clinical Studies

While this debate is in the field of medical research, it is taken up here because it involves issues of gender in research. The importance of the question on the exclusion/inclusion of women with childbearing potential (henceforth to be referred to as WCP) in clinical trials can be contextualized in two developments: the evidence-based medicine (EBM) movement and the women's rights movement. Ironically, EBM while not associated with the women's rights movement, the latter can draw arguments from EBM for the inclusion of women in clinical trials.

Evidence-Based Medicine (EBM)

For a larger ambit, evidence-based practice (EBP) is used to include other fields in health care such as nursing and public health. There are scholars, however, who point to the conflict between EBM and EBP (Fischer and Ferlie, 2013). The Cochrane Collaboration global network, leading international research centers, and even the pharmaceutical industry have embraced EBM as the gold standard (cf Research Funding: Ethical Aspects). The medical insurance industry in the west is now basing its payments on whether or not the intervention used EBM standards. EBM is defined as "the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients" (BMJ Editorials, 1996).

In EBM, there is less reliance on individual practitioner's experience and judgment (believed to have high degrees of uncertainty) and more on formal evidence from quality research with high certitude as basis for best practice. Critical appraisals of evidence from the literature is a central method in EBM where evidence is assessed according to a hierarchy of validity through meta-analysis, statistical tests, or double-blind random trials. Outcomes from population trials are applied to individual patients.

In EBM, decision making on interventions should be guided by the following: effectiveness, safety, efficiency (cost and benefit ratio), and ethics (cf Therapeutic Effectiveness Assessment: Approaches in Contemporary Research).

Exclusion of Women in Clinical Trials

The exclusion of women in clinical trials has been historical (Prout and Fisch, 2001). Rogers and Ballantyne (2008) reviewed 400 clinical trials involving Australians and found that more women than men are included. That women are overrepresented in clinical trials is a controversial subject in the literature (see Prout and Fisch, 2001, on this controversy). However, according to Holdcroft (2007) EBM may be fundamentally erroneous due to the absence of research tools on sex differences. If EBM is to be consistently applied, no drugs that have not been tested by gold standard methods on WCP should be given to them (Holdcroft, 2007; Jones, 2009). But the fact is this is being done quite commonly.

Due to the exclusion of WCP in many drug trials, physicians do not have enough robust evidence to use medication for pregnant women. There is very little reliable information on the safety of drugs for pregnant women both for the women and physicians (Lipman, 2006).

Why Are WCP and Pregnant Women Excluded in Clinical Trials?

There are ideological, scientific, legal – and ironically – ethical explanations. Ideologically, it is the bias that what is good for men is good for women (Eckenweller, Feinholz et al. in commentary submitted to WMA in 2008). Scientifically, the hormonal changes in women could confound findings. Legally, there is fear of potential legal suits against researchers (and study sponsors) (Society for Women's Health Research, n.d.), (i.e., by women participants who suffered miscarriage during the trial). And ethically, it is to protect the fetus from potential harm. The fetus is now included in the list of vulnerable groups and in the case of pregnant women, it is the fetus who is considered the actual vulnerable population (Prout and Fisch, 2001). To protect the fetus, WCP and pregnant women must be excluded. The fact that many pregnant women take maintenance medication, for example, means that "they are essentially participating in an uncontrolled and unmonitored experiment for which the data will most likely never be assessed" (Berlin and Ellenberg, 2009).

The HIV/AIDS crisis challenges this norm when HIV+ pregnant women cannot participate in antiviral trials. To many of these women, the risks of harm are outweighed by the potential for treatment of the disease (Berlin and Ellenberg, 2009). While there is now more awareness about the question of women's exclusion and attempts to include women in clinical studies (Epstein), the general pattern remains exclusionary rather than inclusionary. The arguments for their inclusion are grounded on justice, science, and ethics. Those who advocate for the inclusion of WCP in clinical trials as a matter of policy argue that exclusion puts WCP at great risk when they take medication whose safety for them has not been established scientifically. The very reason for excluding them is in fact the very reason why they must be included: the pharmacologic effects of the medication including dosing must include their specific hormonal and physiologic characteristics during pregnancy when physicians make decisions (Prout and Fisch, 2001).

There must be respect for women's decision making, their ability to weigh the risks, and benefits where clear and adequate information is given to them. "The net effect of gender bias in medical research is that women are at risk for adverse drug reactions and may unnecessarily suffer and die. Such adverse reactions occur approximately twice as often in women as in men" (Schiebinger, 2003: p. 976).

It is injustice against pregnant women to be placed at risk of harm both for them and their babies when they take medication the safety and effectiveness of which have only been established for males. The ethical argument for exclusion flies in the face of the fact that no one is actually being protected because "exposure to a drug being tested is merely delayed until the drug is released and on the market" (Society for Women's Health Research, n.d.: accessed 30.12.13.).

It is in accordance with justice and ethics that WCP and pregnant women are not made to bear the burden of risks simply because science and funders have not given enough attention (and investment) in developing appropriate scientific methods and tools.

The Feminist Association for Bioethics (FAB) in a commentary solicited by the WMA calls for revisions in the DoH guidelines (Eckenweller et al., 2008) that will explicitly and proactively ensure the inclusion of WCP in research that will directly benefit them. Barriers to participation of marginalized groups should be addressed. Exclusion cannot be justified on the basis of potential harm to the fetus alone. Potential harm can be scientifically established with more studies on animals and humans, and how physiologic and hormonal specificities affect the pharmacologic processes of the drugs. FAB also suggests that where WCP are recruited, information about possible termination of pregnancy, or long-term medical followup, and the requisite use of contraception should be clearly explained by researchers when soliciting consent (cf 11029).

Reforms

There have been reforms to address the discrimination against WCP in clinical trials. For example, the DoH, in Principle 13, says, "Groups that are underrepresented in medical research should be provided appropriate access to participation in research" (cf Ethics for Biomedical Research Involving Humans: International Guidelines). The US NIH in 1993 issued the policy that all its grants must ensure that women and members of minorities and their subpopulations are included in all human subject research; for Phase III clinical trials, ensure that women and minorities and their subpopulations be included so that variations in the effects of the intervention are determined; and that cost cannot be used as a reason for exclusion. The NIH Office of Research in Women's Health maintains a database on the inclusion of women in NIH-funded trials.

The US FDA and the Centers for Disease Control and Prevention have also made similar policy reforms.

But reforms have not been enough. The US NIH funds only about 20% of clinical research with the rest of the funding coming from private groups such as the pharmaceutical industry. While there has been more participation of women in clinical studies, this is not enough. What is needed is sex-specific analysis that can determine specific pharmacologic effects such as response to the drug, adverse events, and drug interactions.

It is also recommended that women's inclusion is not limited to Phase III trials because the correct dosage and use of drugs are usually established in the earlier phases (SWHR, n.d.; Prout and Fisch, 2001).

Political Economy in Women's Exclusion

It is more costly, more lengthy, and more inconvenient for researchers to include WCP (Schiebinger, 2003). The physiologic differences between men and women could mean larger sample sizes (Prout and Fisch, 2001). Women who become pregnant may require long-term followup that could include counseling. Women's caregiving roles could increase dropout rates. Women tend to have lower insurance coverage than men because they are more likely to work part time (Prout and Fisch, 2001).

Gender and Technology: From Exclusion to Inclusion?

Vivian A Lagesen, Norwegian University of Science and Technology, Trondheim, Norway

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by J. Wajcman, volume 9, pp. 5976–5979, © 2001, Elsevier Ltd.

Abstract

The field of gender and technology is a rather broad interdisciplinary scholarly field that has existed for more than 30 years now. It includes various aspects of technology and its social and cultural relationship with men, women and gender. The most prominent strand of research has been feminist technology studies (FTS), which has been more or less connected to science and technology studies (STS). This strand has engaged scientifically as well as politically with the *exclusion* of women from many technological areas and spheres. However, there have also been more optimistic strands of research in this field, for example so-called cyberfeminist studies, which have focused on technology as a means for the *inclusion* of women. Alongside such approaches, a social shaping approach has studied the mutual and reciprocal *social shaping* or *coconstruction* of technology and gender. These three narratives – exclusion, social shaping/ coconstruction, and inclusion – have been the most dominant and important perspectives or narratives in this field, and are the point of departure for this article. In the end, I will propose a fourth emerging narrative/theoretical perspective in the field, drawing on *material feminism*.

Introduction

The field of gender and technology is a rather broad interdisciplinary scholarly field that has existed for more than 30 years now. It includes various aspects of technology and its social and cultural relationship with men, women and gender. Even if it is a dispersed and multifaceted field, its scholarship has given particular attention and concern to particular technologies with regard to gender. These are Information and Communication Technologies (ICT), reproduction and biomedical technologies, and household technologies. The most prominent strand of research has been the field of feminist technology studies (FTS), which is related to science and technology studies (STS). This strand has engaged scientifically as well as politically with the *exclusion* of women from many technological areas and spheres. However, there have also been more optimistic strands of research in this field, which has focused on technology as a mean for *inclusion* of women, for example so-called cyberfeminist studies. Alongside these studies there has been a social shaping approach that has studied the mutual and reciprocal *social shaping* or *coconstruction* of technology and gender. These three narratives, exclusion, social shaping/coconstruction, and inclusion have been the most dominant and important perspectives or narratives in this field and will be the point of departure for this article. In the end I will propose a fourth emerging narrative/theoretical perspective in the field, drawing on *material feminism*.

The Exclusion Narrative

The field of gender and technology emerged from a feminist scientific and political concern to investigate the impact on technology on women's lives. Historically, the interest in the study of gender and technology developed from the second wave of the feminist movement at the end of the 1970s and the beginning of the 1980s, when there was a particular interest in the gendered power dimensions of technology. One important source of inspiration was the Marxist-inspired studies of industry, capitalism and labor (e.g., Baxandall et al., 1976; Braverman, 1974). Thus, the early historical accounts of men's domination of industrial technology were framed in terms of power (Cockburn, 1981) and leaned on Marxist accounts of labor process change, but also on object-relations theory from psychoanalysis. Many feminists wrestled with what Heidi Hartmann (1979) called 'The Unhappy Marriage of Marxist and Feminism.' The early feminist studies of technologies brought up a range of different challenges and potential opportunities for women's development of new technology. The most prominent ones were household technologies. These studies raised questions such as, did innovation in household technologies liberate women from household tasks? (Bose et al., 1984; Thrall, 1982; Vanek, 1974). Although contested, the answer was, and has continued to be, predominantly 'no' (Bittman et al., 2004). Ruth Schwartz Cowan's (1983) classic work of women's history shows that modern middle class women, despite the obvious technological changes in household appliances (most of them presumably labor-saving), worked as long if not as hard in their home as before. They just struggled to keep up with ever-higher standards of cleanliness.

An important concern in feminist technology studies has been the consequences of new reproduction technologies for women's lives. The quest for opportunities brought forward by biomedical technologies started with Shulamith Firestone's (1970) famous book, which argued that patriarchy was imposed upon women through their biology and the restrictions that pregnancy, childbirth and child-rearing entailed. She imagined human reproduction taking place in laboratories, thus emancipating women from their biological burdens by means of technology. Different biomedical technologies have been seen to represent new opportunities for women to control and also to design reproduction, to be able to choose when and how to have children, or whether or not to have them at all (Clarke, 1988; Casper and Berg, 1995; Thompson, 2005). On the other hand, both in a critical patriarchal perspective and in an ecofeminist perspective these technologies have

been interpreted as a way to control women and their bodies, as technology in itself has been considered a masculine project to control women and nature (Merchant, 1980; Mies and Shiva, 1993; Wajcman, 1991).

Another important issue has been the exclusion of women from technology and particularly the consequences and causes of women's lack of participation in the producer side of technologies (Faulkner and Arnold, 1985; Cockburn, 1983). Also, men's and women's (different) relationships to machines have been investigated (Cockburn, 1981; Form and McMillen, 1983), as well as the disqualification and degradation of women's work (Phillips and Taylor, 1980) and the polarization of men and women's job when new technologies are introduced (Feldberg and Glenn, 1983).

Two areas in which the exclusion of women has been seen as particularly severe have been in engineering (Frehill, 2004; McIlwee and Robinson, 1992) and computer science (Margolis and Fisher, 2002). Both areas/fields have been perceived as enacting 'masculine cultures.' The question 'why so few' has been, and still is, the most common one. There have been different answers to this question, but usually one or several deficit-models have been drawn upon. Women's 'deficits' have been one common explanatory model (in both feminist and nonfeminist literature). It has been argued that women lack interest, skills, courage, motivation, etc. and the solution is to inform/encourage more women to make their way into these areas. Deficits in the culture, meaning either a 'chilly culture' with discrimination and harassment of women and/or a 'masculine' culture that makes women feel alienated, have often been described and used in explanations (McIlwee and Robinson, 1992; Wajcman, 1991, 2004).

Thus, in many ways there has been a rather pessimistic view of technology as patriarchal, malignant and fostering the exclusion of women. Also, the narrative of exclusion has been – and still is – the most common one in the literature about gender and technology as well as in reviews of the field. What has been seen as the source of men's domination of (and with) technology has been a debated issue. Is it due to men's interests and motives, and patriarchal structures, or is there something inherently gendered about technology? Quite early on, feminist studies of technology became occupied with explaining the exclusion of women by showing how technology in itself was gendered. Berg and Lie (1995) polemically asked 'Do artifacts have gender?', a question which they answered affirmatively. But what does that mean? *How* do artifacts have gender? Does technology always have gender? And how might or should we study technology and gender?

The Social Shaping/Coconstruction of Gender and Technology

The most common answer to the last of these questions has been the idiom of *coconstruction* or *mutual shaping*. Feminist studies of technology have been deeply inspired by social constructivism, especially the social construction of technology approach (SCOT), and by ideas about the mutual shaping of society and technology, and of technology and society as a 'seamless web.' The main tenets of the coconstruction idiom are quite simple: a reciprocal interaction, where two dependent variables or a set of variables interact or influence each other simultaneously to create new outcomes. Feminist studies of technology have produced a substantial body of groundbreaking empirical research in a wide range of areas concerning women and technology. One such area of concern is with women's everyday uses of technology, in which women are usually at the receiving end but not of the design of the technologies they use (Faulkner and Arnold, 1985; Berg, 1996; Cockburn and Fürst-Dilic, 1994; Lie and Sørensen, 1996). Another has to do with technological 'genderscripts': technology designed to cater to men's or women's particular needs, or rather to the designers stereotypical configurations of these needs (Oudshoorn et al., 2002). Faulkner has termed the first issue gender *and* technology and the second gender *in* technology (Faulkner, 2001).

There have been two major ways of which gender and technology has been seen as coconstructed or mutually shaped: one focuses on the designers' role, and the other is concerned with the users of the technology. The main ideas of the coconstruction approach is illustrated in two exhibitions on gender and things (Oudshoorn et al., 2002). The first exhibition was from an idea that emerged during a workshop on gender and technology at the University of Twente, and was organized first on campus, and then later by the science museum in Amsterdam. Later, the same exhibition was set up at the campus at the university in Trondheim. The authors of the article accompanying the exhibitions proclaim that their goal was to show how things are inscribed with gender, "in order to make people aware that we live in a technological and gendered culture" (Oudshoorn et al., 2002, 472). Oudshoorn et al.'s article uses two approaches to do this. The first one is called a 'genderscript' approach, which draws on Akrich's (1992) concept of technological script. The gender script approach is seen to entail two processes of gendering; one is the gendering that takes place through a 'configuring' of a particular version of masculinity or femininity. The producers or designers anticipate the user's preferences, motives, tastes and skills, combined with general cultural norms, and materialize them into a technological object. The design, then, produces a mutual shaping of gender and technology. The next process is that these artifacts are seen as shaping and defining the agency of men and women:

> Due to the norms and values that are inscribed into a technical artifact, objects can attribute and delegate specific roles, actions, and responsibilities to their users.
>
> (Oudshoorn et al., 2002, 473).

The initial exhibition in the Netherlands focused on how designers and other actors were involved in the construction of gendered artifacts. The examples shown were shavers from Phillips, bicycles and microwave ovens from a famous study of Cockburn and Ormrod (1993) (see also below). In addition, the exhibition included a section on objects and artifacts that transcended the traditional separation between feminine and masculine. For example Dr. Marten shoes (once shoes for English policemen that were later used by girls disassociating themselves from the social imperative to be pretty). Further, these are all described as studies of the mutual shaping of gender and (technological) artifacts.

The second approach focuses on how users 'domesticate' technology (Lie and Sørensen 1996). Domestication is a concept that has been used to capture what happens when users integrates the technology into their daily lives. It consists of practices as well as symbolic work. In this perspective users are perceived as active agents in shaping technology, rather than passive adopters of the designer's scheme. Instead of adopting the script, users can choose to alter, modify, or even reject it, thus creating a whole new pattern of use. Domestication is also described as a reciprocal process that changes both people and the technological objects they use (ibid: 478), thus involving a coconstruction of gender and technology.

Faulkner (2001) takes a slightly different approach to the coproduction of gender and technology. While arguing that a mutual shaping of gender and technology occurs, she differentiates between what she calls gender in technology and gender of technology. The latter includes the gendered *associations* that are made in relation to a particular technology, and is based on a different kind of symbolism that connects to different kinds of technology. This symbolism for example is associated with a gendered division of labor (see also Sørensen and Berg, 1987 for a similar argument). The argument is that a technology is perceived as 'feminine' or 'masculine' depending upon who 'normally' uses it. This perspective opens up a substantial degree of interpretative flexibility. For instance, Faulkner shows how a computer keypad was seen as masculine by those who associated it with mathematics, assuming that it something that more men than women would use. Others associated the keypad with data entry, a stereotypical women's activity. On the other hand, Faulkner also stresses that in practice many sociotechnical arrangements are quite stable, irrespective of the theoretical potential for fluidity. Another example put forward by Faulkner is the labeling of technology with gendered language that refers to it as male or female. According to Faulkner (2001, 83), this also reinforces heteronormativity in the sense that it enacts heterosexual relations as 'normal.'

The gender *in* technology perspective focuses on designers and producers of technology. Some artifacts may be designed according to the designer's assumptions about gender. One example that is frequently used to illustrate this is Cockburn and Ormrod's (1993) study, which shows how the microwave oven was originally designed and marketed as a 'brown good' product like televisions, videos and hi-fi systems. It was first designed and marketed for men, assumed to be single and not particularly keen to cook. When this market failed, the producers decided to change the microwave and its configured user. The newly targeted group was women and families/couples shopping for their kitchens, and the microwave was redesigned for 'serious' cooking and sold as 'white goods' appliances such as stoves, refrigerators and freezers.

The gendering process in this case involved symbolic associations as well as a strict division of labor (women cook, men do not). 'Brown goods' were associated with men and men's enthusiasm for technology, and even the sales personnel were men. When the microwave was placed in the 'white goods' department, it was depicted as 'feminine.' Also, managers thought that customers would want to buy white goods from a saleswoman, rather than from a man. Thus, Cockburn and Ormrod (1993) showed how perceptions of gender roles were projected onto the microwave oven, thus making it into a gendered artifact.

Another example is Berg's (1996) study of the design of so-called smart houses or automated homes. This case also is referred to frequently as an important exemplar of coconstruction. Berg shows that the designers of the houses, men engineers, imagined themselves as users of the houses ('I-methodology'), and their design of these houses did not include technological solutions to ease household work (considered to be women's work). As the male designers left potential household tasks out of the development and design process, the smart house was characterized as a stereotypical 'masculine' construction. Thus, gender was assumed as an integral part of the construction. The underlying, counterfactual assumption was that women would have been less interested in the kind of technological solutions that the men designers favored, such as control and security systems, and would be more interested in automating housework. Again, at the core of Berg's observations was the gendered division of labor related to housework as well as design, and the case illustrates the problem of 'translating' gender to technology (see Sørensen, 1992 for a discussion). The gendering of the technology can only be made by the actors themselves and not by the interpretation done by the researchers.

These vanguard studies and many others show very convincingly how technologies are gendered; in particular, how they are shaped by and linked to the pervasive sexual division of labor. But, these studies have not investigated how gender is constructed and what role technology may play in the production of gender. In other words, the assumed dynamic relationship has not been so dynamic after all. Instead, gender often is invoked as a static, a priori category and also is constructed as a binary opposition. The lack of symmetrical attention in many allegedly coconstructional studies of gender and technology has been criticized; in fact, Ormrod (1994, 32) criticized early feminist work for presuming that "the content and behavior of gender relations is assumed to be common knowledge, and their meanings are stabilized and no longer need to be considered."

Arguably, such a structural lag produces an implicit conception of gender as fixed and nondynamic, opposite to the emphasis on 'doing' or 'acting' in many feminist studies of technology. As Faulkner (2001) points out, there are some technologies that are 'barely gendered at all.' In addition, there is the possibility of flexible interpretation, which means that technology may be interpreted in new and diverse ways.

Other scholars have studied the role of technology as a part of the production of 'masculinities' (Hacker, 1990; Mellström, 2003; see also Faulkner, 2001 for an elaboration of the technologies role for men's gender identities). A key issue in this literature has been how technology plays an important role in men's lives and is used to improve and build their identities, for example within such fields as engineering, mechanics and computer science. Still, many of these analyses treat the masculine gender as static, and they seem to take-for-granted what is considered to be 'masculine' and 'feminine.'

In fact, these deficiencies may be more serious than they appear to be at first glance. While the tendency to treat gender as a static category in relation to technology may be explained

by a feminist tendency to identify and critique patriarchy, it may in fact be even more damaging to feminist goals. Reproducing stereotypical notions of men, women and technology by labeling them 'masculine' and 'feminine' tends to ignore the complexity of the relations within and between them and in turn diminishes the analytical potential for developing new and complex gender–technology hybrids.

What does it mean to treat inclusion and exclusion as points of departure when investigating gender and technology? Perhaps we should turn the question on its head and ask: What has been performed through feminist studies of technology? Undoubtedly, such studies have provided much better understanding of how gender and technology are coproduced in a variety of circumstances, but in practice they still treat technology as a man's domain and as a symbol of masculinity. It may be paradoxical that gender and technology have been massively studied, and yet not much has happened to change the paucity of women involved with technology – the generally low and even decreasing share of women who design and study technology, although there remains substantial number of women who uses technologies. Why has it been so difficult to change the gendering of technology? The modernist assumption usually is to treat critique as a basis for enlightenment: to identify problems as a basis for rational intervention.

As we saw from the review above, this has been a central concern for feminist studies of technology. The postmodern belief is that critique may inform, but the interpretation and action are stable and shifting, thus making intervention more difficult. The question though is: how does this work perform on the public? Giddens' (1976) double hermeneutic illustrates the interaction between those who study and those who are being studied, showing that such a dynamic makes knowledge (as well as action) unstable. So, what is performed by feminist studies of technology? One claim would be that gender and technology are being continuously coproduced by involved actors, and that the accounts of how technology is gendered is potentially fed back to the coproduction circle and also becomes part of it. We may ask whether this contributes to change the gender–technology relationship, or actually reinforce it?

The Interpretation of Numbers

With regard to the process of the gendering of technology, researchers tend to interpret activities and artifacts as masculine or feminine, either based on their appearance (e.g., the exhibitions in the Netherlands and Norway) or on whether men or women enact that process. In short, they assume that what women do is feminine, and what men do is masculine. Accordingly, shifts in the relative numbers of women and men will change the gendering of the activity (Lagesen, 2007; Sørensen and Berg, 1987). An example is the mobile phone, which changed from being masculine to 'unisex.' There are other examples of previously men-dominated areas, such as in medicine, in which an influx of women has made the activity's gendered identity less masculine.

Such examples show some potential for change. But none of these changes was a result of feminist studies of technology. Thus, we could ask: Do artifacts have gender – or do their gendered associations derive from feminist technology studies? In other words, how can we avoid performing a conserving, double coproduction of gender and technology? Research-based accounts of gender and technology/ICT may reinforce the problem we want to solve, in part due to the widespread engagement in unwarranted interpretations of assumed symbolic properties. Also, arguments playing on the concepts of feminine and masculine tend to reproduce binaries that should be questioned. What might we do instead? Are there other possibilities?

Perspectives on Inclusion

Some narratives or theoretical perspectives on gender and technology are based on an inclusive, rather than exclusive, logic. One such perspective has been referred to as *cyberfeminism*. Cyberfeminists tend to take more optimistic approaches to the relationship between gender and ICTs, and claim to observe progress in the inclusion of women in new technological arenas such as the Internet. While cyberfeminists sometimes acknowledge that there are forces that tend to exclude women they also claim that many women have become highly motivated and skilled 'cybercitizens.' Plant (2000) is one of the most optimistic cyberfeminists, in the way she argues that women, computers, virtual reality, and cyberspace are linked together in dispersed, distributed connections – a matrix, which, because of its inherent feminine character, will emerge as a new society that will destroy patriarchy. However, Plant's visions have been criticized as too extreme, and also as essentialist and for lacking critical perspective and even hyping new technologies by overstating the women-friendliness of cyberspace. As Wajcman (2004) has pointed out, cyberfeminism does not bring much to the table in terms of feminist politics, and the approach can be criticized for assigning too much agency to new technology and not enough to feminist politics. Are there other options?

A Fourth Inclusion Narrative: Material Feminism?

Mainstream feminist theory traditionally has not been much occupied with technology, and that topic almost exclusively has been a concern for feminist technology studies. Moreover, feminist technology studies have not been very influential with feminist theory, unlike feminist studies of science that have had more resonance with feminist theory building. Donna Haraway's cyborg feminism (1985) has perhaps been the most successful concept for drawing attention to technology as an integral part of feminism, and her work has been used to include a concern for technology in feminist theory (see e.g., Alaimo and Hekman, 2008). *Material feminism* is an emerging area of interest within feminism, which argues for taking matter and materiality more into account when studying gender (Barad, 2003). This emphasis on materiality draws theoretical initiative in part from science and technology studies, which emphasize nonhuman agency (Latour, 1987) as well as the 'trickster' quality and unpredictability of technology, materiality and nature (Haraway, 2004).

Haraway's (1985) cyborg feminism represents a way of thinking about gender and technology that has more potential

for inclusion. The cyborg figure represents an implosion of human and machine. This perspective suggests a focus on disruptions and ambiguities in relation to gender and technology. It advocates the exploration of the women-computing relationship, paying particular attention to the complexities and contradictions of this relationship, and makes gender less binary and essential than in the coconstruction perspective, which tends to focus on exclusions in the gender–technology relationship. But, given that cyborg feminism is a philosophical perspective, how can we make feminist politics out of it? Some have advocated that a version of actor-network theory (ANT) is a way to study gender and technology (Lagesen, 2012; Ormrod, 1994; Singleton, 1995). A main tenet of ANT is that society is an achievement of actors (human and nonhuman) engaging in producing a variety of associations among human and nonhuman elements, and that we, as researchers, should trace these associations by following the actors. Thus, there is potential in Latour's theory for sociologically studying the role of technology in studying how associations are assembled when people construct themselves and their actions. This resonates with the widely used feminist theory that is concerned with how people 'do gender' (West and Zimmerman, 1987). In both a 'doing' perspective and in actor-network theory, gender as well as technology become an outcome of, and not a starting point for, the analysis. Gender–technology hybrids thus can be seen as outcomes of processes of reassembling associations among human and nonhuman elements. How is this perspective useful for thinking about (and acting upon) inclusion of women into technology? Sørensen et al. (2011) explicitly try out such an inclusive perspective in their analysis of several case studies about women and ICTs. They are inspired by actor-network theory and argue that thinking about inclusion would mean asking questions about why women should be interested in technology (as opposed to why they are not). Focusing on inclusion rather than exclusion may provide better insight into how women-technology assemblages are initiated and stabilized, but also how they are destabilized (Sørensen et al., 2011), thus complicating and disrupting the gender binary. Also, it is obviously easier to design inclusion strategies and politics based on knowledge about what contribute to include women to technology, rather than on what excludes women.

This article is a revision of the previous edition article by K. Plett, volume 9, pp. 5980–5984, © 2001, Elsevier Ltd.

Abstract

This article chronicles the various meanings of 'gender and the law' from nineteenth century 'separate spheres' ideology to present-day legal interventions related to women's rights, sexuality, and LGBT (lesbian, gay, bisexual, transgender) issues. Tracking the different forms of injustice that feminist legal reformers have confronted during the period, it defines and illustrates struggles over gender difference, subordination, devaluation, essentialism, victimization, and normalization. It contains an overview of the major strands of legal feminism, explaining the attributes of liberal, dominance, and cultural feminism as well as newer postmodern theories and theories that focus on intersecting forms of bias, including race, ethnicity, class, and sexual orientation.

Varied Meanings of 'Gender and the Law'

The concept of gender and its relationship to law has fluctuated over time and in different contexts. It may refer to a distinct set of legal rules and responsibilities governing men and women. Use of the term 'gender' (rather than 'sex') often signals that the topic extends beyond biological differences between men and women and includes the legal significance of gender roles, gender norms, and common understandings of masculinity and femininity. As a category, 'gender and the law' has been tied to sexuality and personal identity, also covering laws relating to sexual orientation and gender identity, as well as legal responses to gender 'performances' that turn on how individuals exhibit gender through their appearance, speech, dress, and other outward manifestations.

Separate Spheres and Exclusion

Until the latter part of the twentieth century, one's gender (i.e., one's status as a man or a woman) was a crucial determinant of formal legal rights. Prior to that time, the law largely embraced a 'separate spheres' ideology that relegated women to the private sphere of the home and family, while men dominated the public spheres of work, politics, and intellectual life. 'Separate spheres' reflected the dominant culture's ideal of woman's role, even though it did not match the reality of the lives of many women – particularly women of color and working-class women – who often worked outside the home to support themselves and their families (Kerber, 1988). In tune with the dominant ideology, the law was riddled with explicit sex-based distinctions and classifications, often grounded in stereotypes about the different roles, abilities, and interests of the sexes. Many of the stereotypes attached to women and femininity were disparaging and depicted women as unsuitable for numerous lines of work and most professions. Women were presumed to be weaker, fragile, more emotional, less rational, less competitive, and poor at math and sciences. Accordingly, many elite educational institutions refused to admit women, followed strict quotas, or had more stringent admission requirements for women (Murray, 1971). The separate legal treatment of women, however, was often couched in benign terms and justified by the need to 'protect' women from the harsh realities of public life. During this time, gender determined not only who received financial support after divorce (only women) or who would be conscripted into the military (only men), but also virtually every facet of life subject to legal regulation (Chamallas, 2012).

Marriage, in particular, was a highly gendered legal institution. The very definition of marriage was gender-specific, that is, a union between a man and a woman, excluding same-sex couples from entering into legally recognized marriages. Although by the mid-nineteenth century married women no longer lost their legal identity upon marriage (as they did under earlier 'coverture' or 'marital unity' doctrines), the rights and duties of husbands and wives differed sharply. Men were designated the 'head of the household,' with an obligation to provide financial support to their wife and children. By contrast, women were legally obligated to provide care and household services to their children and their husband. Married women's economic dependence, whether presumed or actual, often meant that they were required to obtain their husband's consent to secure credit or loans or to engage in other financial transactions. The law privileged the institution of marriage by punishing those who had sex outside of marriage, through criminal statutes prohibiting fornication, sodomy, and adultery. Additionally, broad legal restrictions on the sale and distribution of contraceptives and on abortions left women with little ability to control their fertility and the size of their families.

During this period, women were often excluded from or had only a token presence in legal institutions. Very few women attended law school, practiced law, or even served on juries. The proportion of female judges and legislators was also exceedingly small, meaning that men were largely responsible for writing and interpreting the law.

Equal Access and Formal Equality

Although women were afforded the right to vote in the United States (1920) and in most European nations in the early part of the twentieth century (Switzerland was a notable latecomer,

extending the franchise to women only in 1971 (with the last Swiss canton, Appenzell Innerrhoden, allowing women the right to vote at canton-level as late as 1990).), widespread changes in the law affecting women's legal status did not emerge until the latter part of the twentieth century, on the heels of the Second Wave feminist movement. Women's rights advocates in the 1970s emphasized women's similarity to men and argued that because women were the same as men in all relevant respects, they deserved access to public institutions, benefits, and opportunities on the same terms as men. Early reform efforts concentrated on dismantling the intricate system of 'protectionist' sex-based legal distinctions, with an eye toward integrating women into formerly male-dominated domains, including blue-collar jobs, the professions, the sciences, and elite universities. The prominent 'liberal feminist' discourse of the period often centered on individual rights, with the central message that gender should be irrelevant to the distribution of legal benefits and burdens and that persons should be treated as individuals, not as members of a class.

The campaign against the use of explicit gender classifications met with early success in the United States, prompting the US Supreme Court to invalidate a wide variety of gender lines in statutes, for example, striking down provisions that presumed that wives, but not husbands, were economically dependent on their spouses for support. These reforms are commonly referred to as having established a legal system of formal equality, requiring that the form of the law (the law on its face) be gender neutral (Franklin, 2010). Pushing back against separate spheres ideology, another theme of the time was that marriage and motherhood should not be regarded as compulsory for all women. Accordingly, courts began to recognize a woman's right to choose to terminate a pregnancy grounded on notions of individual privacy and autonomy. One enduring legacy of the era was to target difference or the differential treatment of the sexes as a touchstone of inequality, marking as suspicious any scheme that provided one set of rules for women and another set of rules for men.

Substantive Equality and Women's Subordination

By the latter part of the twentieth century, it became clear that formal legal equality would do little to change the lives of most women, as evidenced by such phenomena as the feminization of poverty, working mothers' second shift, and the 'glass ceiling.' To uncover the material or substantive causes of women's inequality, feminist theorists began to revise the concept of 'equality' to mean something other than identical treatment of men and women. They argued that if men and women did not start from the same position, identical treatment of each group might never produce meaningful equality. Feminists of this era targeted implicit male norms underlying facially neutral laws, frequently objecting to standards or rules designed around male needs, male social biographies or male life experiences. They shifted attention to areas in which women's situation differed most from men's, focusing on the legal treatment of pregnancy, rape, sexual harassment, domestic violence, and pornography. The rape law reform movement, for example, targeted male-centered definitions of 'consent' that presumed consent unless the rape victim offered physical resistance. Another target of attack was the common practice of refusing to prosecute date and acquaintance rapes in the absence of proof of overpowering physical force.

Despite their attention to gender difference, most feminist theorists of the time were social constructionists, locating the origin of gender differences in cultural attitudes, ideology, discourse, socialization, or organizational structures. In particular, the influential writings of Catharine MacKinnon sought to explain how the legal system was fundamentally opposed to women's interests and designed to perpetuate male dominance. MacKinnon emphasized the difference in power between men and women and contended that the sexual use and abuse of women was the principal mechanism by which women as a class were subordinated in society (MacKinnon, 1989). Her radical brand of feminism (sometimes called 'dominance feminism') was a driving force behind campaigns in the 1980s aimed at eliminating 'violence against women,' a construct used to tie together many forms of eroticized dominance of women. More recently, the antisubordination framework has gained traction globally, generating new understandings of international law, and new prohibitions against sex trafficking and mass rapes in war-torn and conflict-ridden societies (MacKinnon, 1994). The influence of MacKinnon can also be seen in changes in domestic laws, with the dramatic increase in the number of countries enacting laws against sexual harassment, such as in Israel, which passed comprehensive landmark legislation in 1998.

In contrast to earlier individual rights strategies, the dominance feminist emphasis on subordination is a group-based conception that measures injustice by whether a practice or policy deepens power disparities between men and women in society. Akin to the notion of caste in race, gender-based subordination frequently entails processes of sexual objectification that operate to silence women's perspectives and women's ability to discover and define their own desires and objectives. Somewhat paradoxically, given their deep-seated criticisms of law and legal institutions, antisubordination advocates have often favored legal interventions to curb sexual violence and have proven adept at institution building at both the national and international levels.

Devaluation, Caregiving, and the Work/Family Conflict

Another influential strand of legal feminism that first emerged in the 1980s proceeded from an assumption of gender difference but regarded difference in a positive light. The starting point for these cultural feminists (sometimes called 'relational feminists') is the distinctive ways women tend to approach problems, make moral choices, view the world, and construct their identity. Catalyzed by Carol Gilligan's popular book, *In a Different Voice*, feminists with this theoretical orientation celebrated the distinctive contributions women made to society, singling out women's capacity for nurturing, empathy, and preservation of human relationships (Gilligan, 1982). In contrast to liberal feminism's de-emphasis of the mothering role, cultural feminists supported the maternal role and other traditional activities associated with women.

The interdisciplinary literature in this vein drew a contrast between an ethic of care and connection, most often associated with women, and an ethic of justice and autonomy, most often associated with men. Rather than prioritize the rights of the various parties in a hierarchical fashion, the care 'voice' was more interested in finding solutions that would cause the least harm to all involved. Using the image of the 'web' to portray the cultural feminist approach, writers contrasted it to the image of the 'ladder,' which captured a more masculine mode of reasoning. Eschewing abstraction, proponents preferred to examine the particulars of interpersonal situations and to approach disputes contextually. The pioneers of the emerging field of alternative dispute resolution used cultural feminist theory to place greater emphasis on cooperation, preservation of relationships, and attention to process in an effort to reform the adversarial legal system and produce more positive outcomes for clients (Menkel-Meadow, 1989).

Beyond acknowledging differences between men and women, this vision of women's culture argues for a revaluation of the activities and attributes commonly associated with women and femininity. It is linked to the concept of devaluation, identified as the primary source of gender injustice under this orientation. Devaluation refers to the cultural assignment of a lower value to an entire category or class of activities cognitively associated with women, such as the devaluation of nursing, caregiving, or feminine behavior. In contrast to difference, devaluation does not typically involve comparing one individual to another 'different' individual, or comparing the treatment of different social groups. Although devaluation may operate to construct a hierarchy, in that a lower value is assigned to a given category or activity, marking it as inferior or deficient, it often operates to disadvantage individual members of privileged groups, such as a man who is a primary caretaker of young children (Chamallas, 2001).

The effects of gender devaluation have been detected in various sectors. With respect to employment, feminist reformers argued that pay scales in predominantly female jobs and occupations were unjustifiably low, reflecting gender bias in evaluating the relative worth of such jobs, given the skill, effort, and responsibility involved. The movement for 'comparable worth' – with the stated goal of upgrading compensation in female dominated jobs – stalled in the United States, but many other industrialized countries have instituted some sort of comparable worth policy, including the European Union, Canada, and Australia (Bowman et al., 2011). Similar efforts have been made to extend pay equity protection to part-time workers, a female-dominated group made up largely of mothers who are often denied valuable fringe benefits, even on a pro rata basis. While the European Court of Justice has ruled in favor of part-time workers' claims, US courts have rejected similar challenges, relying on the formal equality justification that male and female part-time workers are treated the same.

Women's groups have tried to ease the work/family conflict of working mothers by addressing the devaluation of mothering and caregiving activities. Public support for caregiving activities, including paid parental leave, is now the norm in France and other European nations, while the financial burden for caring for children in the United States remains privatized, resting largely on individual parents. In a new species of 'family responsibility discrimination' lawsuits, litigators in the United States have sought to convince courts that workplace discrimination against mothers and other caregivers is a form of forbidden stereotyping that unfairly labels such persons as less competent and less committed to their jobs (Williams and Bornstein, 2008). Because of the perceived inadequacy of laws addressing pregnancy discrimination, many scholars in the United States have pressed for enactment of laws requiring employers to offer accommodations, such as light-duty assignments, to allow pregnant women to continue working during their pregnancy. Such efforts in the United States have generally been stymied, with the legal fixation with formal equality getting in the way of change. Although the term 'devaluation' is now commonly used to signal bias, it has yet to acquire a precise legal meaning and devaluation remains a kind of injury the law has difficulty comprehending.

Complex Identities, Essentialism, and Intersectionality Theory

Since the 1990s, the theme of diversity among women and the complexity of women's identities has captivated gender and law scholars. Earlier scholarship was often preoccupied with making comparisons between men and women, displaying a tendency to overplay the differences between men and women and to underplay the differences among women. Contemporary feminist scholarship has attempted to correct for these overgeneralizations by highlighting the social and theoretical importance of differences among women, most prominently those of race, class, ethnicity, sexual orientation, disability, and immigration status. The salience accorded to differences other than gender has led to the development of new theories about the interaction of various kinds of oppression in society, referred to as postessentialist, anti-essentialist, critical race feminist, or intersectional approaches.

Intersectional legal scholars – most prominently, Kimberlé Crenshaw in the United States – objected to the use of exclusionary terms and techniques that focused attention on more privileged subgroups (e.g., white, middle-class women) while obscuring the plight of marginalized subgroups (e.g., African-American women) (Crenshaw, 1989). In law, the tendency to frame litigation as if 'race' and 'gender' were mutually exclusive categories has meant that women of color were often forced to 'split their identities' and required to choose between asserting a sex discrimination claim or a race discrimination claim, obscuring important features of the case that did not fit within the chosen framework. Intersectional theorists have called for recognition of distinctive forms of discrimination against subgroups of women that arise at the intersection of race and gender, observing that experiences of racism are often shaped by gender and experiences of sexism are often shaped by race. They assert that it is impossible to separate the racial and gender aspects of one's identity, preferring to describe the self in 'both/and' (rather than 'either/or') terms, in order to capture the full extent and meaning of individual and group experiences. For intersectional theorists, both personal identity and the multiple types of discrimination confronting different subgroups is not simply an additive phenomenon (e.g., race discrimination plus sex discrimination), but an interactive

process, that, for example, gives rise to distinctive brands of racialized sexism.

The intersectional approach is alert to the danger of regarding women as a monolithic group and assuming that all women share certain essential common experiences (Barlett and Rhode, 2006). Gender essentialism refers to the tendency to presume commonalities among all groups of women and to mistake the part for the whole by, for example, making sweeping statements or generalizations about women based on the situation of the most privileged subgroup of women. In many contexts, essentialism exaggerates the importance of gender bias as compared to other forms of discrimination and subordination. When unaddressed, essentialism can tarnish feminist-inspired reforms, rendering them inadequate to meet the needs of large numbers of women. In the United States, intersectional critics have charged that the standard liberal feminist analysis of separate spheres ideology failed to recognize that feminine traits of passivity, dependence, and fragility were culturally associated with white women only, missing the stereotyping of black women as too domineering, rather than too passive and weak. Similarly, they charged that dominance feminism failed to analyze black women's distinctive experience of rape and mistakenly assumed that black women's experience was merely a more intense version of white women's experience (Harris, 1990).

Intersectional scholars have also critiqued the form of essentialism that tends to set Western feminism as the standard for judging women's condition throughout the world. They maintain that the widespread belief that the 'West is the best' creates a danger of misjudging a society from the outside and is too quick to condemn unfamiliar practices associated with the Third World and immigrant populations. Western observers may thus be predisposed to attribute sex-subordinating practices in other countries as stemming from their culture, while regarding incidents of sexual violence in the West as aberrant, reflective of the behavior of deviants rather than constituting part of Western culture itself. The tendency to see 'culture' only in others has the dual negative effect of portraying Third World women as helpless victims of their culture and obscuring the structural and political causes of sex-subordinating practices in other cultures (Volpp, 1996).

Recent intersectional feminist scholarship has taken a comparative turn, investigating high-profile gender and law controversies around the globe. Scholars often aim to understand how women negotiate their multiple identities in different legal and political environments, for example, the gendered struggles over laws restricting the wearing of headscarves ('hijabs') in France and Turkey. In France, Muslim girls and young women have acted against a backdrop in which the predominant French view regards the hijab as a symbol of female subjugation, while the predominant view among Muslim religious authorities considers the hijab to be a symbol of female modesty and religious fidelity to Islam. Between these countervailing forces, Muslim girls and women have defied legal prohibitions against wearing hijabs, choosing to affirm a complex identity that rejects the opposing subjugation/modesty labels and exhibits pride in being both French and Muslim (Wing and Smith, 2006). In Turkey, women found themselves caught in a masculine power struggle between the secular government and male Islamist leaders, struggling to express an identity that opposes the state's compulsory deveiling of women, yet resists Islamist demands to cover and lead a traditional, private life. To disrupt the dominant narratives, they have refashioned the headscarf, pairing it with form-fitting, fashionable jackets and raincoats to signal a complex identity that is both modern and religious (Vojdik, 2010).

Activists have embraced intersectional theory as a tool of social mobilization and to influence public policy. Organizing under the banner of promoting 'social justice,' grassroots groups linked feminism to other movements for social justice in the United States and globally, targeting oppression of social groups and larger systems of inequality and concentrations of wealth (Kalsem and Williams, 2010). In the United States, a reproductive justice movement, which appeals to younger women, has reframed the debate from a narrow right to choose to a more material and affirmative conception of women's reproductive health and freedom. Reproductive justice advocates urge increased access to birth control and abortion, funding for prenatal care, support in childbirth and postpartum, support for breast-feeding mothers, availability of child care for infants and toddlers, income support for caregivers, and high-quality public school education (West, 2009).

While still in the early stages, intersectional theory and its activist offshoots have demonstrated a capacity to forge coalitions among progressives and to create some of the necessary conditions for broader social and legal change. One drawback is that intersectional scholarship is not always 'coded' as 'gender and the law' scholarship. Instead, it is often categorized as scholarship relating to race, ethnicity, or social class (but not gender), missing a key point of intersectionality theory and setting it apart from other developments related to women and sexuality.

Agency, Sex-Positive Feminism, and Victimization

In the twenty-first century, many feminist writers have recoiled against stereotyped portrayals in the popular culture and mass media of women as passive sexual objects, perpetually vulnerable to violence or exploitation. Placing the blame partially on the influence of Catharine MacKinnon's brand of dominance feminism, critics have sought to redirect the focus away from sexual violence and what they regard as a fixation on women's victimization. Paralleling the move to study intersectional and multiple forms of oppression, revised accounts of the complex nature of personal identity seek to present women as simultaneously victims of oppression and agents of their own destiny. There is a renewed emphasis on women's 'agency,' meaning the capacity to direct one's own life through individual action and choice. Related to the concept of autonomy in liberal theory, the concept of agency highlights women's ability to resist, make decisions, and contribute to the cultural meaning of gender in society.

One strand of the new autonomy-focused feminism, called 'sex-positive' feminism, has set out to reclaim the pleasures of sex and sexual agency for women and to distance itself from accounts of sex as an inevitable site of danger for women. It stresses the importance of female sexual desire and pleasure

and charges that dominance feminist accounts of sex as dangerous for women have played into the hands of social conservatives who continue to regard sex as something to be indulged in only for purposes of reproduction. One prominent writer remarked that feminists have gotten stuck in 'No' and have yet to theorize why women say 'Yes' to sex (Franke, 2001). Sex-positive feminism resonates with a younger, 'third-wave' generation of feminists who often embrace a 'fun, playful aesthetic,' that finds joy in 'make up, feminine styles of dress, and traditional "girlie" behavior' (Crawford, 2007). Third-wave writers are more apt to cast pornography in a positive light, arguing that pornography is not invariably bad for women. In this view, pornography allows some women to connect to their sexual feelings and acquires meaning only through the person who views it.

Other critics of victimization concentrate on complicating the account of women's agency beyond the sexual sphere. They have highlighted the contexts in which women are often required to make strategic choices – and exercise what is called 'partial agency' – against a backdrop of subordinating structures and ideologies (Abrams, 1995). Trying to break through the victimization/agency dichotomy, legal practitioners have developed concepts, such as 'separation assault,' to provide a fuller description of the situation of women who are battered by spouses or other intimates. They have explained how batterers often intensify their violence to prevent a woman from leaving or to retaliate against her for leaving. Such accounts challenge the stereotype of the 'battered woman' who suffers from 'learned helplessness' and is too terrified to act. They emphasize the strategic choices women make when they decide whether to stay in or to leave a relationship (Mahoney, 1991).

Critics of victimization are often wary of the benefits of legal intervention. They advocate pulling back from the law, for example, the deregulation of pornography or the elimination of mandatory arrest and no-drop laws that disregard the victim's wishes in domestic violence cases. The emergence of such new forms of legal feminism has deepened the split between legal feminists who are ready to enlist law to further a feminist agenda and those who mistrust the power of law and the state and are skeptical of legal entanglements.

Postmodernism, Identity Performance Theory, and Normalization

Lagging somewhat behind their counterparts in other disciplines, contemporary legal feminist scholars have generated a body of scholarship that bears the hallmarks of the larger intellectual trend known as postmodernism. Postmodern legal feminists explore gender not as an essence but as a social process, specifically, the process of assigning meaning and significance to gender differences. Postmodernists place paramount importance on language, discourse, and habitual social practices to explain how gender differences and gender deviancy are constructed in a given culture. In law, they have questioned the conventional legal understanding of gender identity as an ascribed or fixed status, focusing instead on the 'performative' dimensions of a person's identity. They examine, for example, how individuals present their 'difference' in a variety of settings through dress, language, personal style, and everyday behaviors.

This fluid, non-status-based account of identity multiplies the range of identities a person may project, making it possible to speak of an individual as being more 'black' or more 'gay' in certain contexts. In contrast to earlier brands of legal feminism, postmodern legal feminism tends to shift focus away from the existence and maintenance of gender hierarchies to analyze the sex-based categories themselves, particularly the dominant conception that the sexes are opposite and that there are only two sexes, that is, men and women. They contend that instead of being natural, binary conceptions of sex and gender are socially constructed, with individuals being conditioned through everyday social practices to perform their gender in binary ways. Scholars have explored the 'policing' of the boundaries between the genders, such as sex segregation and the stigmatization of individuals who do not conform to dominant gender norms. Postmodern feminists typically embrace the interrelated goals of destabilizing or disrupting traditional meanings of sex and gender, resisting the binary, and promoting and fostering gender nonconformity.

The postmodern emphasis on 'performing' one's identity has led to a deeper understanding of the dynamics of intra-group bias, a complicated process by which only certain members of a particular group or subgroup are singled out for adverse treatment, while others are able to rise to the top. Thus, an individual may be targeted for discrimination because she performs her identity in ways that call attention to her difference and make those in power feel uncomfortable, for example, the black female employee who wears braids or African-style clothing or socializes mainly with other black women (Carbado and Gulati, 2000). Legal scholars have criticized the demands placed on individuals to assimilate to the dominant norms of an institution or a community, characterizing such demands to 'cover' or downplay one's identity as a central mechanism of discrimination in the twenty-first century (Yoshino, 2002). Performance theorists have also documented ways that minorities and other 'outsiders' are called upon to enact 'racial comfort strategies,' gestures, and behaviors designed to make insiders feel at ease, imposing a special burden that results in extra work, anxiety, and resentment.

Performance theory has provided a valuable tool of analysis in 'masculinities' studies, a subgenre of scholarship of particular interest to legal feminists. Masculinities theorists investigate the multiple ways masculinity is socially constructed in different contexts, focusing especially on how men perform their identity (Cooper and McGinley, 2012). Although most such scholars accept that men as a group exercise power over women as a group, they are most interested in understanding how men achieve and retain power and how power differentials among men can harm some men as well as women. The operative term ('masculinities') is deliberately plural to signify that different groups of men perform their masculinity differently. Masculinities scholars see the diversity of male gender performances as partly a product of differential power, using the term 'hegemonic masculinity' to describe the ideal of masculinity traditionally associated with white, Christian, straight, upper class men. The fundamental tenets of masculinities theory reveal a close connection to

legal feminism, particularly the belief that dominant masculinity norms send the message that masculinity is to be privileged over femininity. Similar to postmodern feminists, they regard masculinity not as an essence but as an ideal that can never be finally possessed or achieved, causing men to be constantly anxious about their masculinity and leading them to engage in aggressive, sometimes destructive, masculinity contests. A recurring feature of men's identity performances is the need to denigrate 'contrast figures,' most notably women, gay men, and racial minorities. Built into the struggle among men is thus an imperative to disparage others, not necessarily to inflict harm on those others, but to win the intramale competition for power and esteem.

These postmodern versions of scholarship have identified normalization as the key problem to address. In this context, normalization refers to discourses and ideologies that simultaneously privilege socially 'acceptable' or 'normal' practices and ideas and marginalize and discredit the 'deviant' lives of nonconforming individuals. Postmodern legal writers typically express concern that even when law is invoked by reformers bent on change, the normalizing discourse of law carries the potential to backfire and reinforce, rather than subvert, dominant ideologies. For this reason, many postmodernists have decidedly deregulatory impulses, often presuming that the law will not forego its reliance on status-based identities and that even feminist-inspired legal reform will cause negative unintended consequences.

Lesbian, Gay, Bisexual, and Transgender Scholarship, Queer Legal Theory, and the Transgender Movement

For the past several decades, legal feminism has been closely tied to scholarship focused on lesbian, gay, bisexual, and transgender (LGBT) issues, a literature that has grown exponentially with the rise of the marriage equality movement. Particularly now that 16 nations and 13 US states permit same-sex couples to marry (writing in August 2013), the field has expanded beyond analysis of specific legal restrictions facing LGBT individuals to development of complex theories that map and explain the nature of cultural forces and discourses inhibiting change. Reflecting the fast-changing developments on the ground, LGBT scholars have struggled with and debated four key constructs that lie at the core of their inquiries: sex, gender, sexual orientation, and gender identity. Early LGBT theorists warned against conflating the first three categories, insisting that one should not presume that a person's sex (i.e., biological sex) determined his or her social style (gender) or choice of sexual partner (sexual orientation) (Valdes, 1995). Until the recent transgender movement, however, little attention was paid to 'gender identity,' defined by the medical profession as a deeply felt psychological sense of sex that departs from the sex assigned to a person at birth. Transgender (or 'trans') scholars have since argued for a more fluid concept of gender identity that encompasses not only transsexuals desirous of sex-change operations and medical interventions, but also a broader class of gender variant or gender nonconforming individuals whose gender identities may shift over time and who may even identify as neither male nor female (Vade, 2007).

Queer legal theory is a popular new strain of scholarship that rejects identity-based categories, such as heterosexual and homosexual, and envisions freeing people from the constraints of identity. Like other performance theorists, queer scholars often shift the focus from what individuals 'are' to the various ways individuals 'do' or 'perform' their sexuality or gender. In its reclaimed form, the term 'queer' signals a disdain for, and opposition to, dominant norms of sexuality, gender, intimacy, and kinship, often placing queer theorists against marriage and conventional family formations (Romero, 2007). Many queer theorists profess a positive stance on sex and are critical of laws or legal reforms that address sexual conduct as a moralistic restriction. This prosex commitment often leads them to affirm expressions of sexuality in all its forms and to value individual freedom over equality. Some queer critics have gone so far as to distrust legal parties' claims of sexual injury in sexual harassment or rape cases (Halley, 2002). Queer theorists' investments in sexual pleasure, including the 'dark' pleasures of sexual domination and submission, have often pitted them against dominance feminists who have used the law to eradicate exploitive or nonmutual sexual practices. This tension threatens to sever the historic alliance between feminist and LGBT constituencies (McCluskey, 2009).

Conclusion

Since the latter twentieth century, theorists and activists who operate under the banner of 'gender and the law' have identified a variety of different 'enemies' as the principal source of injustice facing women and other marginalized people. Early efforts called for eliminating gender differences between men and women, attacking women's subordination, and addressing the devaluation of women's culture and activities commonly associated with women. These foundational theories primarily compared men to women and were aimed at promoting women's equality, albeit defined in different ways.

In contrast, contemporary theories have embraced a more complex view of gender and its relationship to law. They recognize that women are a highly diverse group whose lives are affected by other aspects of their identity, that women are not only victims but exercise agency and choice, and that gender is a fluid concept that assigns meaning to myriad social practices. These newer theories have targeted new 'enemies,' cautioning against essentialist discourses that presume that all women share common experiences or that trade on simplistic portraits of women's victimization. Influenced by postmodernism, many recent writers have reconfigured the field of gender and law away from an exclusive focus on women to a new terrain that critiques normalizing discourses and ideologies that limit the freedom of nonconforming individuals whatever their gender. While the complex theories of the twenty-first century have enriched the field of study, they have also uncovered new tensions, particularly among those who advocate using law as a vehicle for change and those who distrust legal intervention and fear the unintended consequences of legal reforms.

Abstract

Gender and women's studies refers to scholarship about and the academic study of the meaning and implications of gender and gendered roles across society, including a focus on power, oppression, and the intersection of identities. As an interdisciplinary field, it draws upon, addresses, and adds to topics covered by all of the hard and social sciences and the arts. In this article we discuss the development of women's studies as an academic field; its intellectual backgrounds and offshoots; the current state of the discipline; current academic programs, methodological issues and problems; and emerging directions in theory and research.

Gender and women's studies refers to scholarship about and the academic study of the meaning and implications of gender and gendered roles across society, from arts and culture, to politics and the economy, to education, to philosophy and religion, and to the hard sciences. These studies include a focus on power, oppression, and the intersection of identities. Gender and women's studies have historically had a lens that privileged a white, middle-class, and US-based perspective, but over the past 25 years has increasingly focused on experiences outside of this narrow range through discussions of intersectionality as well as through a focus on 'Third World' women. Gender and women's studies originated as an academic field in the 1970s as a spin-off from the second wave of feminism.

Overview

Women's Studies, also referred to as Gender Studies or Feminist Studies, is the interdisciplinary study of how intersectionality of gender, race, age, class, nationality, ethnicity, ability, sexuality, and other differences impact almost every facet of the social, political, and cultural experience. The basis for the academic field of Women's Studies was laid in the student, civil rights, and women's movements of the 1960s and 1970s, when women in academia argued that academic knowledge production failed to recognize gender as a lens of analysis. Many women, concerned about the often inaccurate and disparaging patriarchal narratives about them, seized the opportunity presented to them in the 1960s and 1970s to tell their own stories. Women took advantage of their formal educated status and the cultural atmosphere of radical, social, and political uproar to insist on a more systematic and potentially transformative narrative about women's lives. The discipline examines how gender not only influences popular culture and private life, but also impacts laws and social policies. By examining a cross section of disciplines such as political science, sociology, literature, psychology, and other subjects, Women's Studies seeks to understand gender roles in past and contemporary societies. Women's and gender studies also examines how the lives of individual women and men are shaped by broader structural forces in both historical and contemporary contexts, for e.g., nation building, globalization, economic developments, and the legal system. Women's Studies continues to reflect in its curriculum and faculty research the constantly changing directions that multiple First and Third World feminisms are taking today.

Women's Studies is an interdisciplinary field that examines socially- and culturally-defined gender roles. Drawing upon academic areas such as history, psychology, media sociology, sociology, literary criticism, and anthropology, it crosses the boundaries of traditional disciplines raising important questions regarding the way we have organized ourselves, our chief social and political institutions, and knowledge itself. As an area of academic study, Women's Studies provides new frameworks that are sensitive not only to issues of gender, but also race, class, and ethnicity. By analyzing the powerful and problematic impact of sexual inequalities, Women's Studies revises the way we see ourselves and our world. Because of the growing importance of women's concerns globally, undergraduates with a concentration in Women's Studies are well prepared for professional programs in law, medicine, and business, as well as graduate programs in social work, education, and arts and sciences. Indeed, students who major in Women's Studies, whether or not they choose to go on to professional or graduate school, are especially well positioned to work in education, policy institutions, development, media, social work, and the private sector.

Even though Women's Studies is a relatively new phenomenon in higher education, it is today well established as an interdisciplinary field of study, which draws on knowledge from both the humanities, the social sciences, medicine, and natural science. Today the field's interrogation of identity, power, and privilege go far beyond the category 'woman.' The first Women's Studies course is purported to have been created by American historian Mary Ritter Beard, who in 1934 constructed a 54-page syllabus for a course titled *A Changing Political Economy as It Affects Women* (Tuttle, 1986). Although the course was never taught, it prepared the foundation for the development of the first Women's Studies program in the United States. The first Women's Studies department was founded at San Diego State College (now San Diego State University) in 1970. At San Diego State, the on-campus Women's Liberation group formed a committee with faculty and community members called the Ad Hoc Committee for Women's Studies. The group collected hundreds of petition signatures in support of a Women's Studies program. In 1970, five San Diego State faculty members from existing departments taught courses related to Women's Studies. In the fall of

1970, the first Women's Studies Department was officially approved. By 1974, San Diego State had begun a national faculty recruitment to strengthen the Women's Studies Department. By the 1974–75 school year, the once fledgling department had two full-time and four part-time faculty and an enrollment of nearly 400 students. The Women's Studies department continued to grow, and in 1995 began offering a master's degree in addition to the bachelor's degree. The program also hosts a Women's Resource Center on campus. The second Women's Studies department was created at Cornell University in 1970 as well. Cornell's program was renamed Feminist, Gender, and Sexuality Studies in 2002.

Women's Studies has made the conceptual claims and theoretical practices of intersectionality, the study of how modes of identity such as race, class, and gender, and the sociopolitical construction of inequality are mutually comprised and must continually be understood in relationship to one another, and transnationalism, which emphasizes cultures, structures, and relationships that are formed as a result of the movement of people and resources across geopolitical borders, foundations of the discipline. Eventually Women's Studies was institutionalized into thriving academic programs across the country. Currently there are over 600 academic Women's Studies programs that offer minors, majors, and even graduate degree options. As a discipline, Women's Studies is concerned with achieving a level of equality for women in society. This dedication to systemic social change makes Women's Studies scholarship feminist and links the discipline to social movements that seek to end practices of inequity such as sexism, racism, and heterosexism around the world.

The place of Women's Studies within the academy has, of course, always been highly contested. Within the university, the discipline was said to not be academic enough. At the same time, however, feminist activists outside of the academy argued that the discipline was being too academic. Moreover, Women's Studies was further problematized by the emergence of disciplines like gender studies, and queer, transgender, and postcolonial theories in the 1980s and 1990s, which challenged the very category of 'woman' and called into question the founding premises of its identity politics. This social activism appears to have given way to academic practice as the dominant mode of 'Western' feminism at the turn of the millennium. However, the goals of the women's movement have not been fully endorsed. Women still strive to address issues such as equal pay for equal work, free childcare, and autonomy of sexuality.

Intellectual Backgrounds

The intellectual backgrounds of gender and women's studies began in the West with discourse about the equality of women in the late-eighteenth century (Donavan, 1991). Two strains of conversations emerged, one in the former Colonies and one on the Continent, but both centered on growing disquiet about the unequal legal, political, and economic status of women. The interaction of changes in wealth and technology with Enlightenment-based revolutionary thought allowed upper-class women access to education and ideas that caused them to question their roles in the political, economic, and social structure of the day, while lower-class women began leaving the home for outside word as industrialization spread.

The most fundamental argument that the first feminists addressed concerned women's legal status. Men were considered heads of households, and women and children were considered his property, and thereby denied property, legal, and political rights. Thus when Elizabeth Cady Stanton drafted the *Declaration of Sentiments* in 1848 declaring that men and women were essentially equal with respect to natural rights and thereby should be granted legal, political, and social rights, including suffrage, she was proposing changes that were simultaneously radical and moderate, in that while women's inclusion in these arenas would fully disrupt the social, economic, and political structure of the day, the philosophy upon which these proposed changes are built were comparable with the accepted beliefs about men's rights.

The focus of intellectual development about women and their role in society during the last half of the nineteenth century and into the first quarter of the twentieth century focused on the potential and role for women's inclusion in public decision-making through the franchise. In conjunction with Stanton, Susan B. Anthony led the start of the women's suffrage movement, whose most famous quote was "Resistance to tyranny is obedience to God." The early women's suffrage movement quickly included women's organizations that also focused on prohibition, and the argument was that because of women's central role in the home and their charge to protect the family, women should be allowed to vote so that they can also help the prohibition movement. Female antisuffragists countered that this central role in the family was anathema to entering the public sphere through voting. Through Westward expansion, the notion that women were intellectually and physically less capable than their male counterparts was weakened, and this argument was further deteriorated through the roles that women took over during the war efforts during World War I. The American women's suffrage movement was radicalized through the experiences of some of its leaders taking part in the suffrage movement in Europe, and the work of women like Alice Paul forced open the political opportunity structure allowing the Congressional and state strategies led by Carrie Chapman Catt to lead the movement to victory.

The strides in the understanding of gender and gender roles made by these early feminists were significant but limited. Advances in understanding the nature of gender diverge at this point, and these divergences were significantly influenced by emerging intellectual traditions in Europe and the New World. These traditions include transcendentalism, Marxism, existentialism, psychoanalysis, and the works of Freud.

Cultural feminism grew out of the transcendentalist movement and focused on the tight bonds between women and the potential for the development of a matriarchal culture. No writings of the time capture the spirit of this tradition more than Charlotte Perkins Gilman's *Herland*. Gilman describes a community of women cut apart from the rest of society for over a 1000 years that survived by asexual reproduction. The women existed in harmony with each other and nature, escaping the trappings faced by women in Western patriarchal societies, and romanticized notions of woman as nature. Cultural feminism laid the groundwork for later feminist offshoots, including Essentialism and radical separatism.

Marxist feminism developed through an extension of the Marx–Engels analysis of the nature of oppression extant between the bourgeoisie and the proletariat. Marxist feminists contend that the nature of oppression does not emanate from the separation of workers from the means of production, but instead from a more fundamental form of oppression, that of women by men. These feminists argue that all other forms of oppression develop out of this fundamental one. Probably, the chief contribution of Marxist feminists to the second wave of feminism was a focus on the hidden economy of housework.

Feminist reactions to Freud have been largely negative, rejecting what is seen as biological determinism (as well as fundamentally misunderstanding female biology) and bias in favor of masculine superiority. A strand of feminism, nonetheless, developed around psychoanalysis that focuses on the developmental role of individuals becoming part of a familial system. A key distinction is made in this line of analysis that explains gender differences based on men's and women's different preparations for adult life, in the market (capitalist production) and in the home (reproduction), respectively. The role that language plays in this system is to undergird and reproduce gendered oppression.

The roots of feminist existentialism come from the works of Simone de Beauvoir who extends the Hegelian dialectic to gender, noting that in gendered systems male becomes the positive and norm, whereas female is defined in opposition to him as the Other. Extensions of feminist transcendentalism focus on women's liberation through the destruction of the self as other. Here, language becomes important in the active renaming of self and the creation of women-centered communities and societies.

A common thread in both the Marxist and existentialist feminist traditions is throwing off oppression through consciousness-raising and an intentional focus on marginalization and otherness. By locating perspective and analysis from the outsider position, the development of a fuller analysis becomes possible, thus increasing the potential for liberatory efforts. In neither of these traditions do the primary proponents limit themselves to otherness based in gender only, and extend their understanding of oppression to race, ethnicity, class, and social position (Alcoff and Potter, 1993).

The second wave of feminism developed out of women's participation in the Civil Rights movement and the reaction of many movement leaders to gender-based organizing. Initial calls for a separate women's movement focused on the destructive roles of marriage, love, rape (as both an interpersonal tool of subjugation as well as a more widespread political tool of subjugation), pornography, imperialism and colonialism, and work. A radical separatist arm of the movement developed that focused on alternative family structures. Simultaneously, an arm of the second wave of feminism developed by women of color and focused not only on their exclusion by leaders of the Civil Rights movement, but by the white leaders of the women's movement and a movement ideology focused primarily on the issues and problems faced by middle-class white women as well. But the winner of these battles were the liberal feminists who focused on making incremental changes through court challenges and legislation under the premise that with the exception of gestation and childbirth, women are the same as men and therefore laws should develop to ensure equality of opportunity.

By the mid-1980s the women's movement began experiencing backlash and with it significant critique. Among the critiques were that the movement was developed for and about the needs of middle-class, primarily heterosexual white women. Third-wave feminism developed from these critiques, with a rejection of the male–female dichotomy in favor of a more nuanced understanding of both gender and sexuality, and a greater emphasis on the perspectives of women of color and embracing Grrrl and Queer theory. The intellectual core of third-wave feminism is the idea of intersectionality, or the idea that the multiple forms of oppression in society are interactive and interconnected. Intersectionality is an extension of the focus on identity politics and standpoint theorists in the 1980s and is used for analysis, critique, and movement development.

Current State of the Discipline

As a discipline, Women's Studies programs faced challenges in the early years and Women's Studies professors have had to challenge statements about the purpose and necessity of their programs. In the early years there were no Women's Studies 'departments' or funding for those who wanted to teach Women's Studies courses. The first Women's Studies faculty had to create a new discipline: they had to create their own textbooks, compile reading lists, develop new curricula, and establish journals. These newly developed courses provided the first opportunity for women's lives and experiences to be studied critically in the academy from a gender-sensitive point of view. Furthermore, these faculty members drew upon a new pedagogy that was more participatory and personal and later became known as feminist pedagogy. For a number of the all-male colleges and universities that became newly coeducational during the 1970s, Women's Studies programs were created as a way of incorporating and integrating women into the campus community. These new courses also offered faculty and students the opportunity to conduct in-depth scholarly work on subjects that had previously not been a part of the college curriculum, or were at the margins of more traditional disciplines, such as domestic violence, women's roles in historical periods, and women's literature. Moreover, given its origins in the women's movement, Women's Studies was from its beginnings activist in its design. The goal of the discipline was not 'disinterested' academic inquiry, but was clearly focused upon ending of oppression against women and challenging traditional paradigms.

Academic Programs

Growing rapidly as a discipline, by 1975 there were about 150 Women's Studies programs in the United States. Academic programs in women's and gender studies include a range from nondegree course offerings, to undergraduate certificates, to academic minors, to bachelor's degrees, to graduate certificates, to master's degrees, and to doctorates. In addition, many academic institutions allow students enrolled in interdisciplinary studies programs to develop their own emphasis on gender issues. Women's studies courses frequently fulfill general education requirements for undergraduate degrees. Among these institutions, many also include women's centers.

These nonacademic units frequently offer student development and support programming and activities beyond the academic approach.

Using a variety of resources and web-based lists, we see a range of these programs across the United States. (These include http://www.artemisguide.com/; http://userpages.umbc.edu/~korenman/wmst/prog; rams.html; http://www.smith.edu/swg/graduate.php; http://creativefolk.com/directories.html; and www.nwsa.org.) While there are over 600 programs in the United States, Alaska is the only state without a formal degree program, and there are several states with only one or a handful. The state with the most institutions with degree programs in women's and gender studies include New York with 43 and California with 41. Among these programs there are roughly 350 with academic minors, 50 with undergraduate certificates, 200 that offer a bachelor's degree, almost 50 that offer a graduate certificate, and another 50 that offer a master's degree, and about 20 doctoral programs (though there are more doctoral programs that offer interdisciplinary programs of some sort through which a concentration in gender or women's studies is possible).

Both the academic programs and the resource centers are supported by a variety of groups, but chief among them is the National Women's Studies Association (NWSA). NWSA was established in 1977, includes both individual and institutional members, and receives additional support from a variety of private foundations. NWSA hosts both national and regional meetings, hosts constituency groups, promotes the advancement of women's studies in education through task forces, and facilitates caucuses for underrepresented groups within the discipline (see www.nwsa.org for more information).

Outside of the United States, degree-granting women's studies programs exist in every region, though not in every country. By far the United States has the most degree-granting programs, followed by Canada with 45 and the United Kingdom with 34. Programs exist in every country in Western Europe, as well as many others in Eastern Europe and some in the former Soviet states. There are a handful of programs in Asia, South America, Africa, and the Middle East.

Journals

Among mainstream academic journals, there currently exist over 100 that focus on gender and gendered issues specifically. Among them, they focus on a variety of social sciences, arts, business, and law. However, the most common type of these journals is interdisciplinary, which include a variety of topics. With the exception of one journal on geography and about 10 concerned with women's health and health care, there are no hard science journals focused just on gender and gendered issues. There are a little more than a handful of journals with a specific focus on people of particular ethnic backgrounds, and these focus on women and gender issues related to people of India, Asia, African-American, Middle East, and Nordic descent.

Research

Trends in academic literature tend to follow the availability of journals with some notable exceptions. The major issues that gender and women's studies focus on contemporarily include: reproduction and reproductive rights; criminal justice, particularly interpersonal violence and rape; economic development and justice; intersectionality; LGBTQ rights; gendered roles in the media; and equal representation in leadership and economic institutions. Much of the literature does not take on one topic at a time, but instead takes up many of these themes simultaneously.

Recent examples from the journal *Signs* demonstrate overlap among these areas (see Table 1). Most notably, an analytic framework focused on intersectionality as opposed to patriarchy dominates most analyses, and combines other theoretical traditions within women's studies to traditional academic fields, particularly within the liberal arts and social sciences. Typically, the literature does so by focusing on one traditional field, reflecting the reality that while there are doctoral programs in women's and gender studies, most feminist scholars are trained and hired into these more traditional fields and use a feminist analytic frame to guide their scholarship.

Criticisms and Methodological Issues

As a discipline, Women's Studies sought to empower women to take an active role in creating and critiquing the language about and reality of women's existence. Women's Studies devotes itself to the study of women, whose experiences have been neglected in conventional scholarship. However, the discipline faces strong criticism from several areas. For example, Pat Robertson was quoted in a fund-raising letter stating that "The feminist agenda is not about equal rights for women. It is about a socialist, anti-family political movement that encourages women to leave their husbands, kill their children, practice witchcraft, destroy capitalism, and become lesbians." Others critique the activist nature of the discipline, arguing that it is inappropriate to develop an academic discipline based on a liberatory agenda, which necessarily requires a biased analysis as opposed to a value-free or neutral analysis.

While these assessments of the discipline are far from accurate, Women's Studies has differed widely over time and across institutions. Always centered on the experience of women, the status of the feminine, or the construction of sexual difference, gender or women's studies theorists have addressed an array of patriarchal underpinnings that have tainted the way that we view various issues. Women's Studies demands that through interdisciplinary investigation we reconstruct the very way we think about thinking, rejecting the normative claims of positivism that it is possible to have a truly value-neutral investigation of anything.

As seen in Table 1 (below), the methodological approaches taken by most gender and women's studies primarily rely on either analysis of text for critique and theory development or through qualitative data collection and analysis. Since the second wave of feminism, a common analytic approach employed by women's studies and gender scholars revolves around feminist critical theory. Feminist critical theory or literary theory developed as an analytic tool to simultaneously understand gender in text and to develop liberatory projects. To a lesser extent, feminist scholars will engage in quantitative analysis primarily utilizing gender as a dummy (dichotomous)

Table 1 Examples of recent scholarship

Area	*Recent examples*	*Major question*	*Fields*	*Methodology*
Criminal justice	McKim (2014)	How do gender-sensitive treatment programs inside and outside of the criminal justice system compare?	• Criminal justice • Intersectionality • Psychology • Marginality	Ethnography
	Fili (2013)	How does the binary view of females in prison as either victims or resisters frame how we understand identity?	• Criminal justice • Political theory • Epistemology • Identity	Theoretical reflection; case study
Equality	Akchurin and Lee (2013)	How do forms of women's activism, professional, labor, and movement impact earnings cross-nationally?	• Development • Economic inequality • Social movement theory • Sociology • Political science	Surveys; quantitative modeling
Culture & norms	Sallee (2013)	Within the higher education setting, what role do gender norms play on men's involvement at home?	• Gender norms • Higher education • Business, management, and leadership	Interviews; case comparison
	Durham et al. (2013)	What is the state of the field of hip-hop feminism?	• Popular culture • Black feminism • Intersectionality	Review of literature; theoretical reflection
Intersectionality	Cho et al. (2013)	What is the potential for the development of a new field of intersectional studies? What are the dynamics of scholarly intersectional studies compared with applied change models?	• Intersectionality • Political science • Social movements • Feminist theory • Advocacy	Theoretical reflection
	Patil (2013)	To what extent has the shift from patriarchy to intersectionality in feminist theory been made?	• Feminist theory • Transnational scholarship	Theoretical reflection; case study process tracing

variable to understand the differences in behavior, responses, beliefs, and opinions between men and women. While a more common approach taken by scholars in traditional departments, particularly in fields in which quantitative analysis is given primacy over qualitative analysis, this approach flies in the face of the central tenants of third-wave feminism and their understanding of gender as a range of attributes as opposed to a binary opposition.

Current and Emerging Directions in Theory and Research

The focus of women's studies has changed significantly over time. Early scholarship focused on documenting the state of being female – what do women do; where are they (and where are they not); how are they treated. The focus quickly shifted to an analysis of why, usually accompanying advocacy for positive change. This focus on why also delved into the nature of gender and gender distinctions.

The continued growth in Women's Studies has been attributed to two major trends in higher education – the growth of a diverse student body increasingly older, female, racially and economically diverse, first-generation college students, and the differently abled; and a movement to transform the traditional academic curriculum into one that is more expansive and inclusive. Women and gender studies draws upon an interdisciplinary core that places women's diverse experiences and the issue of gender at the center of inquiry. One of the prominent contemporary trends in the field of Women's Studies is the model of incorporating intersectionality – race, class, gender, and other dimensions of human identity – into research.

Though topics such as sexuality, reproductive health, race, and equality continue to dominate the discipline, there are two significant and emerging themes in the discipline. The first focuses on the representations of children, children's experiences, and children's place in the world. The rights of women are often discussed around the question of their biological capacity to bear and raise children. Children's identification and development represents an emerging trend in women's and gender studies. The second is a reimagining of solidarity, or the act or expression of unity in the face of power. Solidarity is an open-ended concept, but at the most basic level it implies a community based on mutual responsibility of each member toward the other, and a moral obligation to fight for the welfare of other members and of the community as a whole. Contemporary feminist reifications of solidarity as an important quality of the movement harken back in some ways to the traditions of the early cultural feminists as well as the radical separatists of the 1970s but in this iteration place a greater emphasis on inclusivity.

Gender Development: Cultural Differences

Deborah L Best and Kelsey L Luvender, Wake Forest University, Winston-Salem, NC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explores culture-based differences in gender development. In spite of the noticeable differences seen in clothing and other somewhat superficial behaviors, there are indeed many similarities between men and women within various cultural groups, along with notable differences in gendered behaviors across cultural settings. This article examines the role of culture in the development of gendered behaviors, looking at both proximal and distal factors that affect gender development in various cultural settings.

Culture and Gender

The role of culture is often overlooked in discussions of gender roles and biological differences are usually considered the primary source of influence. Yet, visitors to other countries and cultures are often struck by the obvious gender differences they see in the clothing and behavior of women, men, girls, and boys. Western visitors in predominantly Muslim countries quickly notice that women are more 'modest' than men, covering more of their bodies with long dresses, headscarves, hijab, or burqa. Indeed, when South Asian visitors arrive in Western countries wearing their saris or dhotis, they encounter women with bare shoulders and midriffs, short skirts, and high heel shoes, and men in sport coats, trousers, and neckties. In spite of these differences in clothing, and that globalization has made blue jeans and tee-shirts standard fare around the world, one wonders whether differences in clothing reflect differences below the surface. Are women and men, girls and boys different in different cultural settings?

Before proceeding, it is useful to define several terms. *Sex* usually describes the anatomical and physiological differences between males and females, which are often considered to be the biological basis of observed gender differences. *Gender*, on the other hand, is a more subjective term and is used to describe the psychological and behavioral differences between males and females. The development of gender-related behaviors and beliefs are influenced by cultural practices and beliefs, such as what tasks children are taught, the clothing they wear, and the division of labor within the family (Whiting, 1963; Whiting and Edwards, 1973). In spite of the distinctions made between sex and gender, across the lifespan biological and social influences on the development of gender roles and identity are inseparable and it is not always easily distinguishable (Fausto-Sterling, 2000; Hoyenga and Hoyenga, 1993).

Viewing gender development through the lens of probabilistic epigenesis demonstrates the interplay between genes, the sociocultural environment, and evolutionary processes. The probabilistic epigenetic framework emphasizes the reciprocal influences within and between the levels of the organism's *developmental manifold* (genetic activity, neural activity, behavior, and the physical, social, and cultural influences of the external environment) in the realization of observable phenotypes (Gottlieb, 2002).

Proximal and Distal Influences on Gender Development

Although developmental psychologists often categorize factors that influence gender development as proximal and distal, these are not orthogonal categories and indeed are somewhat overlapping and interactive. Distal factors within the macrosystem (Bronfenbrenner, 1989) are culture-wide and objectively are shared by many if not all people within a culture. They are often represented by global comparison statistics (e.g., United Nations, World Health Organization, Organisation for Economic Co-operation and Development), which are assumed to be consistent across the culture or country being described. The political system and government regulations, the national economy and labor opportunities, dominant religious organizations and beliefs are among the distal macrosystem factors that can differentially influence women and men within and between cultures. Along with these more structural cultural characteristics there are also prevailing social norms and expectations for 'proper' gender role behaviors. Children grow up within this complex of distal influences that shapes their gender-related learning and experiences.

In contrast to these distal influences, proximal microsystem developmental factors are more individualized and may differ between families or specific groups within a larger culture (Bronfenbrenner, 1989). Although distal aspects of the culture may influence or be represented within the proximal factors, they are not subjectively experienced in similar fashion by all members of the society. Within a single cultural setting, for example, there is often wide variability in resources and opportunities between families and individuals; not everyone is rich, nor are they rich to the same degree. When a country experiences an economic downturn, the subjective experiences of people at the top and bottom of the economic scale differ. Low-wage earners may lose their jobs and homes while high-income families simply eat in restaurants less often. These distal and proximal factors make up the developmental niche (Super and Harkness, 1986), the ecocultural framework (Bronfenbrenner, 1989) within which gender development occurs.

Proximal Biological Influences on Gender Development

Setting the stage for cultural influences within the developmental manifold are the proximal biological factors that lay the

foundation for gender differences to develop. Sex differences between females and males are found in sex chromosomes, hormones, neural structures, physical size and strength, activity levels, and secondary sex characteristics. These biological differences are often considered to be immutable and the hallmarks of gender differences. Yet, there is considerable variation across cultural settings in how these differences unfold and are perceived. Behaviors and developmental milestones have long been considered biologically driven, such as infant sleep patterns or the onset of sitting and walking. However, these sorts of behaviors have been shown to vary across cultures and are influenced by parental practices and ethnotheories about child development (Super and Harkness, 1986). Along with inheriting genes, children also inherit parents, peers, and the places they inhabit. Thus, it should not be surprising to find that gender development is influenced by the sociocultural context.

Proximal Cultural Factors in Gender Development

Along with biological influences on the development of sex and gender, culture, a vital part of the developmental manifold, provides a context in which biology unfolds. Around the world, children grow up within the cultural context of the family – the developmental niche composed of the physical environment where the family lives, the parents beliefs, or ethnotheories about what children are like and how they should be cared for, and the actual care they receive from the mother, father, siblings, and others within the family circle (Super and Harkness, 1986). As should be obvious, girls and boys may be treated differently across these different cultural contexts.

Gender Socialization and the Role of Parents

Gender socialization is the process by which cultural information about gender is transmitted from one generation to the next within the ecocultural context (Best and Williams, 1993; Munroe and Munroe, 1975/1994; Rogoff et al., 1984). Mothers, fathers, siblings, relatives, teachers, peers, and others teach boys and girls the gendered behaviors, values, and roles that are expected or are necessary for living successfully within their cultural setting. At birth (or before given the frequent use of ultrasound), a newborn is labeled a girl or boy, and gender role socialization begins and is shaped by parents' and cultural expectations.

Parents' Expectations about Gender

Parents describe their newborn girls as 'finer' and 'quieter' than boys who are described as 'more coordinated' than girls (Sweeney and Bradbard, 1989). Girls are handled gently and are talked to more than boys who are handled more physically and are expected to be 'tough.' Such parental notions are even born out in 'Baby X' studies where unbeknownst to the parents, they are describing the same baby that has simply been labeled as a girl or boy (Seavey et al., 1975; Sidorowicz and Lunney, 1980). These expectations about girls and boys reflect the parents' memories of their own childhood and how the future will unfold for their child.

However, cultures change with time, and roles and behaviors reflect those changes. Little girls growing up in the United States in the twenty-first century will certainly have many different opportunities than did their mothers or grandmothers. They could become engineers, air force fighter plane pilots, or champion soccer players, roles unavailable to their grandmothers. Similarly, cultural changes have made it more acceptable for boys in the United States to grow up to be preschool teachers or stay-at-home dads. Likewise, Zinacanteco parents in Mexico have expectations for their children based on their own experiences and interpretation of their world (Greenfield et al., 1989). To prepare their children for their future roles, Zinacantec parents sometimes give gender-appropriate objects to newborns, such as green chilies to boys who are expected to know how to buy them as adults.

Culture shapes the way that parents interpret the child's biological sex characteristics (e.g., 'It's a girl.') and how they treat the child. The names that girls and boys are given, how they are dressed and cared for, what behaviors are considered appropriate, and what tasks and roles they are taught are among the many ways that culture influences gender. Children grow up within parents' culturally derived scripts (e.g., girls should learn to be obedient, boys should be brave and not cry) that assume continuity in the expectations and experiences that parents and children encounter. These scripts guide children's behavior long before they understand their own gender label or appropriate gender role behaviors.

Culturally based scripts and expectations shape the way that girls and boys are socialized. In their classic study of socialization practices in more than 100 societies, Barry et al. (1957) found that girls are usually reared to be nurturant, obedient, and responsible while boys are reared to be independent, self-reliant, and achieving. These differences are often referred to as the expressive and instrumental constellation of traits, which are assumed to be bipolar opposites, suggesting important differences in the socialization of boys and girls. However, a later reanalysis of these data suggested that these dimensions are independent, rather than opposite ends of one dimension and that both boys and girls are socialized to be independent and self-reliant (Hendrix and Johnson, 1985). These studies suggest that when looking within various cultural groups, differences in the way that girls and boys are socialized seem to be consistent across cultures. Yet, bear in mind that cultures certainly vary in how differently girls and boys are socialized. Girls may be reared to be more independent and self-reliant in one culture than are boys in another culture.

Mothers' and Fathers' Roles

Among the gender influences found in the family context, an important socialization mechanism is found in the differential roles and modeling provided by mothers and fathers. Weisner and Gallimore (1977) examined parenting roles in 186 societies and found that mothers, female adult relatives, and female children were the primary caregivers of infants, though siblings of both sexes were often caring for younger children. Although children generally see mothers as responsible for children, in some cultures 2- to 4-year-olds spend more than 70% of their time with child caregivers. In these cultures, mothers are actively contributing to the livelihood of the family and even young children are expected to assume responsible roles (Mintern and Lambert, 1964).

In comparison with mothers, fathers generally spend less time with their infants and young children and they participate

less in childcare (Katz and Konner, 1981; West and Konner, 1976). Both boys and girls see fathers' role as breadwinner and mothers' as responsible for the domestic realm, and these beliefs persist into adolescence (Goldman and Goldman, 1983). Best and colleagues (Best et al., 1994) confirmed these beliefs when observing parents and children on playgrounds in three European countries. Mothers in France, Italy, and Germany showed more caregiving behaviors than fathers, but French and Italian fathers engaged in more play than mothers. Indeed, Lytton and Romney (1991) found that fathers pay less attention to daughters than sons. Fathers tend to be more important as caregivers of sons (Rohner and Rohner, 1982), but mothers are equally important as caregivers of sons and daughters. When observed in public places, girls are seldom found with fathers or adult males, but boys are often found in all male groups and these differences increase with the age of the child (Mackey and Day, 1979).

Although fathers in most cultures have less direct contact with their infants and young children than do mothers, they do play an important role in gender socialization. Fathers are more likely than mothers to reward children for gender-appropriate behaviors and to discourage cross-sex behaviors, particularly for sons (Leve and Fagot, 1997). Indeed boys 'get the message' and they report that their fathers would think it was 'bad' if they play with cross-gender toys (Raag and Rackliff, 1998). Boys believe that their fathers have more restrictive rules than their mothers, but girls do not share this belief. When fathers are absent for long periods of time, boys display effeminate behaviors, dependence, excessive fantasy aggression, and overly masculine aggression (Gronseth, 1957; Lynn and Sawrey, 1959; Stevenson and Black, 1988; Stolz, 1954).

In contrast to these typical gender differential patterns of parenting is that found among the Aka forest foragers (Hewlett, 1992, 2000). Among the Aka, adults and children forage together caring for family needs. Men and women participate in collaborative net hunting and sex roles are egalitarian. Women are held in high esteem and food preparation and childcare are not considered feminine activities. Aka fathers are with their infant children 88% of time compared with !Kung and Logoli fathers who are with their infants 30 and 9% of the time, respectively. Aka fathers are affectionate caregivers for infants and children, not playmates, and they do not engage in rough-and-tumble play. Aka infants and fathers become attached and seek each other out. A different pattern of parenting is found among the Hadza, hunter-gatherers of East Africa, as well as among other African agricultural groups. Compared with the Aka, the Hadza are more gender stratified and fathers do not participate in childcare (Marlowe, 2005).

These different parenting strategies show the variability in how parents and children adapt to the demands of their physical and social ecological settings. Fathers can be nurturant caregivers and mother can be playmates and disciplinarians. As would be expected children who see their parents perform cross-gendered behaviors (e.g., fathers cooking, mothers washing the car) are less aware of gender stereotypes and show less preference for stereotypic adult occupations (Turner and Gervai, 1995).

Differential Treatment of Girls and Boys

When looking at actual parenting behaviors, Lytton and Romney (1991) found in their meta-analysis of 172 studies involving more than 27 000 children that there were few systematic differences in parents' rearing of girls and boys. In the North American studies, both parents encouraged gender-typed activities and characteristics, with fathers showing more gendered expectations than mothers. In 17 Western countries, boys received more physical punishment than girls, but disciplinary differences decrease with age. Fathers were more likely to use physical punishment, particularly for boys, and mothers were more likely to reason with children and explain rules and consequences (Conrade and Ho, 2001; Russell et al., 1998).

There appear to be only minor differences in the ways that parents treat girls and boys. Often studies comparing mothers and fathers behavior with their children observe them in the same, relatively representative settings. Yet, there are certainly different behavioral expectations and constraints for parents and children relative to the setting. Lindsey and Mize (2001) observed parent–child dyads in pretend and physical play settings. Mothers engaged in more pretend play with their daughters and fathers in more physical play with their sons, and these play patterns predicted similar play patterns observed with children and their peers. When parents were observed helping their preschool children on a balance beam, mothers were equally attentive with daughters and sons, but fathers were more protective of daughters (Hagan and Kuebli, 2007).

Weisner and colleagues (Gallimore et al., 1993; Weisner, 1984) developed the concept of 'activity settings,' which highlights the behavioral consequences of children's culturally regulated social settings. In Kenyan families that divided time between urban and rural settings, mothers were more nurturant toward their young sons when they were in their crowded Nairobi apartments than when they were at their farms. The Munroe and Munroe (1971) also demonstrated the effects of household density on Kenyan Logoli mothers' behavior when looking at infant caregiving. Infants in households with many potential caregivers were responded to more quickly when they cried, but they received less care from their mothers who were usually busy with gardening or other household tasks. The Munroes point out that in many cultural settings infant caregiving is a system, often with multiple caregivers, rather than the function of a single one-on-one caregiving relationship.

Thus, it appears that there may be subtle differences in how parents treat daughters and sons, and occasionally these differences are statistically significant. Yet, it is likely that the same parental treatment could affect girls and boys differently, particularly in transitional developmental periods, such as toddlerhood or adolescence, when new abilities are emerging (Beal, 1994).

Task Assignment

One of the important ways that children learn differential gender roles is through the tasks that they are taught and asked to perform. The role of the child's learning environment was demonstrated in the classic Six Culture Study that investigated socialization practices with 3- to 11-year-olds in India, Kenya, Mexico, Okinawa, the Philippines, and the United States (Edwards and Whiting, 1974; Minturn and Lambert, 1964; Whiting and Edwards, 1973). Mothers' work determined children's participation in chores, such as carrying wood and

water, preparing food, gardening, cleaning, and caring for younger children and animals. Training for girls began at an earlier age than for boys, girls were engaged in more chores, cared for younger children, and participated in more economic activities than boys (e.g., shelling maize for sale). Boys ran errands were involved in more undirected free play, tended animals, and were further from home than girls.

In the context of these differential learning environments, girls who spent more time caring for infants displayed more nurturance than boys. Boys showed more egoistic dominance (i.e., changing others' behaviors to suit one's own desires) than girls. There were fewer gender differences in the cultures where both boys and girls helped with sibling care and household chores (i.e., Kenya, Philippines, United States) and greater differences where girls did more of these (i.e., India, Mexico, Okinawa). In general, girls had more responsible productive work, and boys spent relatively more time playing. Parents communicate the importance of appropriate gender roles by their reactions to their children's behavior and by the organization of activities within the family.

Siblings and Peers

In addition to parents, across all cultural settings, siblings and peers play important roles in the socialization of gender roles, and their influence tends to increase with age. Boys with older brothers and girls with older sisters have more gender-typed activity preferences than same-sex singletons who, in turn, are more gender-typed than children with other-sex siblings (Rust et al., 2000). For both girls and boys, having an older brother is associated with more masculine and less feminine behavior. Boys with older sisters are more feminine but not less masculine, and girls with older sisters are less masculine but not more feminine. The greater influence of older brothers may be due to the higher cultural value of typical masculine role behaviors than feminine ones. In most societies it is more acceptable for girls to behave like boys than it is for boys to behave like girls (Golombok and Fivush, 1994). Indeed, among school-age children, girls imitate male role models to a greater extent than boys imitate female models (Bussey and Bandura, 1984, 1992). For girls, being a tomboy is relatively common and acceptable in most Western cultures, but for boys, being a sissy is frowned upon.

Peers also play an important role in gender socialization. When toddlers, 21–24 months of age, were observed in free play, both girls and boys received positive responses when they played with same-sex peers (Fagot, 1985). However, when boys participated in typically feminine play, the negative feedback from their male peers directly told them such behaviors were inappropriate and to play with others like you. Girls expressed disapproval of girls who played with boys, but they did not show concern about the types of activities involved. It is evident that male peer groups start defining what is *not male* at an early age, and those activities that are not male quickly drop out of the boy's repertoire.

Maccoby (1998) observed three different ways that gender influences children's social interactions with peers: gender segregation, dissimilarity of boys' and girls' interaction styles, and gender group asymmetry (e.g., boys groups are more cohesive, sexists, exclusionary, and separate from adult culture than girls' groups). Most often, boys are in packs and girls in pairs. These differences are influenced by both biological differences (e.g., boys higher activity levels) and by gender socialization that occurs within the cultural context. As early as 30–36 months of age, children favor same-sex playmates, and gender segregation occurs across cultures and increases with age (Bock, 2005; Leaper, 1994). By age $4^1/_2$, children in the USA spend three times more time with same-sex peers than with other-sex peers, and by age $6^1/_2$ this differential has grown to 11 times more time (Maccoby and Jacklin, 1987).

Similar patterns of peer interaction were found in the Six Culture Study with children as young age two preferring same-sex peers and this tendency increased throughout middle childhood. In these same-sex groups, boys strive for dominance and take more risks, and girls work to maintain positive social relationships and avoid conflict. Gender segregation found in the childhood years is sometimes reinforced by adolescent initiation customs and ceremonies found in many cultures.

Initiation Rituals

Initiation rites and rituals are a socially prescribed way to show others that the initiate has achieved adulthood. Separation from the family and other-sex peers, initiation into adult sexuality, instantiation of male dominance and aggression, and demonstration of peer group and political loyalties are seen in initiation rituals. Group initiation is found more often for boys than girls and in cultures that emphasize adult gender difference (Edwards, 1992).

The pubertal process does not hold a universal definition across cultures. In some cultures the crossover from childhood to adulthood is marked by a biological change, while for others it is more of a social occurrence. In some non-Western societies, 'coming of age' occurs at a particular age with traditional initiation ceremonies that may include male circumcision and female genital cutting. After initiation, the boy or girl is considered an adult and is expected to work, marry, and have children (Herdt, 2010).

The Sambia of Papua New Guinea initiate boys before their tenth birthday as a way of controlling gender roles in their culture. Initiation rites 'defeminize' the boy's body and separate him from his mother (Herdt, 2010). Initiation occurs at age 10 because of the 'emergence of sexual attraction to others' at that age, especially for boys (Herdt and McClintock, 2000). In societies that view sexual behavior as strictly reproductive, adolescents are less likely to feel comfortable engaging in such actions. Yet in societies, such as the Trobriand Islanders and the !Kung people of Southern Africa, sexuality is encouraged as recreational and pleasurable outside of marriage (Herdt and McClintock, 2000).

In Western cultures, there is a noted difference between gonadal puberty, with later onset for boys than girls, and sexual maturation (Herdt and McClintock, 2000). This difference is not typically distinguished in more traditional, non-Western cultures where biological changes are not considered the determinant of puberty. Western cultures recognize pubertal changes that begin around the age of eight as critical for cognitive and behavioral development that leads to mature awareness of sexuality.

In some cultures, unlike many Western cultures, open discussion about sexuality is rare and discouraged. Young Pakistani women report gaining information about their own

sexual development from sources within their immediate home while young men gain information from external sources (Hennink et al., 2005), though the information may be minimal. Sex education is neither taught in schools nor explained in the home in Pakistan. Few Pakistani adolescents discuss pubertal bodily changes with family members, and the majority of those who do are boys. Girls receive little information about pubertal changes in themselves or the opposite sex or how a female becomes pregnant. Pakistani women may only learn about sexuality and reproduction just prior to marriage, which often leads to high anxiety and fear on a woman's wedding night (Hennink et al., 2005).

Parents, siblings, peers, and other socialization agents help shape a child's gender-appropriate behaviors, toy choices, playmates, activities, and gender role behaviors. These proximal influences on gender development occur within the larger cultural context and interact with more distal cultural influences, such as the division of labor and the political and education systems. These distal influences help to shape the stereotypic beliefs that children develop about gender and their beliefs about appropriate gender roles.

Distal Cultural Factors in Gender Development

Division of Labor

With the wide variation in physical settings and environmental demands, it is quite surprising that from rural, subsistence cultures to urban, industrialized ones, there are few difference in the gender-related behaviors that are found. This consistency is usually attributed to the almost universal division of labor within societies. For example, across 244 different societies D'Andrade (1966) found that women were responsible for food preparation and domestic chores, activities consistent with childcare (Brown, 1970; Segal, 1983). In contrast, men were responsible for hunting and activities further from home, with little involvement in childcare (D'Andrade, 1966; Katz and Konner, 1981).

In spite of these consistencies in division of labor, environmental demands modify these distinctions. Van Leeuwen (1978) found that in hunting or gathering societies with low food accumulation, both males and females must contribute to the subsistence of the group, which minimizes the division between the sexes. In such settings women's contributions are valued. In sedentary societies with high food accumulation, the usual division of labor is found, and women's roles involve nurturance and compliance.

Cultural changes in women's fertility rates, opportunities for childcare, and technology have permitted women to increase their participation in the labor force outside the home. However, they still maintain most of their domestic responsibilities, doubling their workload (Dixon, 1978; Population Crisis Committee, 1988). Looking at workforce measures across 56 countries from 1960 to 1980, Jacobs and Lim (1992) found that women's labor force participation and fertility rates were inversely related. Surprisingly, modernization, measured by gross national product and women's education, were positively related to gender segregation and women were paid less than their male counterparts (Ottaway and Bhatnagar, 1988). Even more surprising, in a study in the USA, Great Britain, West Germany, and Austria more educated people and women with employed husbands were less favorable toward gender equality than less educated people or women with no male wage earner (Davis and Robinson, 1991). These findings suggest that the relation between the division of labor and beliefs about appropriate gender role behaviors is a complex one that is influenced by environmental demands, as well as long-standing cultural customs and practices which are embedded within the history, economics, and prevailing religious beliefs of a society (Mukhopadhyay and Higgins, 1988).

Status, Religion, and Political Influence

The multidimensional relations among status, power, and privilege in various cultures are influenced by the physical demands of the environment, and the economic and political organization of the society. As a result, the status afforded women is multifaceted (Mukhopadhyay and Higgins, 1988; Quinn, 1977) reflecting their economic contributions, political involvement, the autonomy, and power of their various positions, as well as the prevailing ideological and religious beliefs that prescribe appropriate gender roles (Best, 2009).

Along with economic activities, men generally play more powerful roles in religious practices and hold more influential positions in political/governmental organizations. Religious doctrines vary greatly in the status and freedoms they grant to women and men and their teachings about appropriate gender relations and roles. However, in the three most predominant religions throughout the world, Christianity, Islam, and Hinduism, religious practices are primarily controlled by men (Browning et al., 2006). When religion and government are largely separate, religious beliefs have less influence on the interactions of women and men. Yet in countries where religious doctrine and governmental authority are closely tied, religious beliefs exert a stronger influence on gender roles and child-rearing practices (Browning et al., 2006).

Across cultures, men's status is consistently superior to that of women (Hoyenga and Hoyenga, 1993; Population Crisis Committee, 1988; Whyte, 1978). Recently, the Global Gender Gap Index 2013, which is independent of the income and resource level of an economy, measured the equitable distribution of available income, resources, and opportunities for women and men. Review of 136 countries demonstrated that no country has yet achieved gender equality. However, all Nordic countries, except Denmark, have closed over 80% of the gender gap, providing benchmarks for international comparison (World Economic Forum, 2013). Similar shift in status and power are occurring in other cultures as well. In the last decade, Ethiopia passed the most progressive abortion laws in Africa to combat unsafe abortion rates, and Mali passed a law that women are no longer required to obey their husbands. Although the status of women's rights and freedoms continue to improve, men are more involved in economic and political activities and possess greater status and power than women.

Educational System and Practices

Certainly one of the most influential mechanism of cultural influence is found in the educational practices endorsed by

a society. Usually within these educational settings, there are cultural messages about appropriate gender behaviors and socialization practices that support them. Parents may value education, both formal and informal, differently for girls and boys. In some, less egalitarian societies, it is considered more important to educate boys than girls. Serpell (1993) found that in Zambia, it was considered more important to educate boys than girls, and even though mothers were responsible for children, schooling for boys was so important that fathers made the arrangements. Similarly, for some traditional Muslim ulama teachings, secular education for girls, especially higher education, is thought to lead them astray. Arab families have a tendency to pay for boys' education but not girls' because they may believe that money spent on boys will eventually be repaid. There is little point in paying for girls' education because girls are destined to become mothers and will not be in careers where they could make money (Faisal, 2003).

Across 48 countries, women who received some education were significantly less likely to be married as children (below age 18) than those who received no education (UNICEF, 2004). Marriage before the age of 18 is a reality for many young women, but education is often seen as key to preventing child marriage. In Zimbabwe, only 4% of girls who had attended primary school were married, compared with 40% of those who had received no education. In many parts of the world, parents encourage the marriage of daughters while they are still children hoping to benefit financially and socially, and also to relieve financial burdens on the family (UNICEF, 2005).

Parents' beliefs about the importance of school as well as their expectations about children's performance greatly influence children's achievements. Mothers in the USA, China, and Japan expect boys to be better at math and girls to be better at reading (Simpkins et al., 2012; Lummis and Stevens, 1990) even though for some aspects of both disciplines, they perform equally well. Boys show greater confidence in mathematics, relative to girls, than would be expected based on the relatively small differences in performance. Yet in most countries girls are more anxious about math abilities than boys (OECD, 2004b).

Teachers treat girls and boys differently in the classroom. Fifth grade teachers in the USA and Japan devote more than half their attention, especially negative attention, to boys than girls. However, this increased attention is not due to more off-task or bad behavior (Hamilton et al., 1991).

In many Western countries over the second half of the twentieth century, girls' educational performance has overshadowed boys' and women's level of education has surpassed men's. According to USA census data, since 2000 women in the USA have held 58% of the advanced degrees (master's, professional, doctoral), and in 2012 37% of women and 30% of men attained a bachelor's degree.

In 21 of the 27 OECD countries for which comparable data exist (OECD, 2004a), university-level graduation rates for women now equal or exceed those for men. In these primarily Western countries, significant progress has been made toward reducing the gender gap in formal education. It is evident that in these cultures the value and importance of education is clearly shifting in relation to the roles and expectations for girls and boys.

Development of Culturally Endorsed Gender Roles and Stereotypes

As a result of the various cultural forces on gender role learning that children experience, they develop culturally derived stereotypes about male–female differences and gender roles. As early as 2 years of age, children in the USA stereotype objects as feminine or masculine (Thompson, 1975; Weinraub et al., 1984). By 3–4 years of age they identify activities, toys, and occupations as appropriate for one sex or the other (Edelbrook and Sugawara, 1978; Guttentag and Longfellow, 1977). Similar gender-related learning takes place around the world (Best, 2013; Bloch and Adler, 1994; Edwards, 2000; Prosser, et al., 1986).

As children are learning about gender roles during the childhood years, they also begin to associate particular personality traits with women and men, such as women are emotional, gentle, and men are strong, dominant. European American children's knowledge of these gender-trait stereotypes increase from kindergarten through high school, with the largest increases during the elementary school years (Best et al., 1977; Williams and Best, 1982/1990). The same pattern was found with 5-, 8-, and 11-year-olds in 25 countries though the rates of learning varied (Williams and Best, 1982/1990). In 17 of the countries, children knew more of the male traits than female, with German children being the only country showing the opposite pattern. There was also evidence that female items were learned earlier in Latin/Catholic countries (Brazil, Chile, Portugal, Venezuela) where the adult female stereotype had more positive characteristics than the male. Gender stereotype trait knowledge was highest in Pakistan where 5-year-olds knew more of the stereotyped items, particularly the male items, than 8-year-olds in other countries. Studies have shown that urban, middle class children who have more educational opportunities learn the global, pancultural stereotypes at an earlier age than their rural, lower class counterparts (Lee and Sugawara, 1982; Montero, 1978; Tarrier and Gomes, 1981). However, as children grow, stereotypes incorporate more gender-incongruent information (Hanover, 2000) and by young adulthood stereotype scores show little relation to education or urban/rural status. Thus, it appears that although culture modifies the rate of learning as well as aspects of content, gender-trait stereotypes are remarkable universal (Berry et al., 2002; Best, 2010). Such similarity perhaps reflects the fact that the relations between females and males are remarkably similar in cultural groups around the world.

Conclusions Regarding Gender Development and Cultural Transmission

Perhaps growing from the biological differences between females and males, cultural practices and traditions evolve and become part of the belief systems that are seen in religion, oral and written history, and the myths and literature of cultures. From these grow expectations about appropriate gender roles and stereotypic notions about the differential characteristics associated with the sexes. These are woven into the framework of the culture and become socialization models for children.

Although the developmental mechanisms that lead to gender-related behaviors may differ across cultures, the more distal ones, such as the division of labor, religious beliefs, political and social status, and the educational system provide the backdrop for more proximal mechanisms, such as socialization by parents, siblings, and peers, differential treatment and tasks for girls and boys, and initiation rituals. Such practices result in the gender-related beliefs, attitudes, roles, and behaviors that are observed in cultures around the world and lead to individual variation as well as differences between cultural groups.

This article replaces the previous edition article by J.S. Hyde, volume 9, pp. 5989–5994, © 2001, Elsevier Ltd.

Abstract

The scientific study of gender differences has yielded a wealth of robust generalizations about the way males and females differ across domains, cultures, and developmental stages. This article provides a descriptive overview of gender differences in personality, social cooperation and competition (including aggression and play), and verbal and nonverbal communication. Qualitative statements about the typical behavior of males and females are supplemented with quantitative data from *meta-analyses* and other large-scale studies. Key methodological issues in the measurement of gender differences are discussed to aid the reader in the interpretation of research findings.

The scientific study of gender differences has a long history, spanning more than a century of research (Ellis et al., 2008). Competing theories of gender vary in the role they assign to evolutionary history, cultural practices, endocrine and neurobiological mechanisms, and individual learning; they also vary in the extent to which they regard these levels of explanation as complementary or mutually exclusive. While the field is rife with theoretical debate and controversy, decades of empirical research have yielded a wealth of robust generalizations about the way males and females differ across domains, cultures, and developmental stages. This process has been accelerated by the diffusion of *meta-analytic* techniques over the last 30 years. Thanks to *meta-analysis*, the results of multiple studies can be aggregated and corrected for various sources of error; also, the effects of potential moderators can be analyzed in detail.

This article provides a descriptive overview of gender differences in personality; social cooperation and competition (including aggression and play); and verbal and nonverbal communication. Whenever possible, qualitative statements about the typical behavior of males and females are supplemented with quantitative data from *meta-analyses* and other large-scale studies. To aid the reader in the interpretation of these findings, the initial section presents and discusses key methodological issues in the measurement of gender differences.

Methodological Issues

The Interpretation of Effect Sizes

In psychological research, group differences (including differences between males and females) are usually expressed in terms of standardized effect sizes. The most common effect size for group and gender differences is Cohen's d, the difference between means divided by the pooled standard deviation of the two groups (e.g., $d = 0.50$ represents a distance of half a standard deviation between male and female means). Conventionally, positive values of d indicate that the male mean is higher than the female mean, whereas negative values indicate that the female mean is higher. Values of d can easily be translated into estimates of statistical overlap (**Figure 1**). For example, $d = 0.50$ corresponds to a 67% overlap between male and female distributions (assuming normality). The precision with which a variable is measured can dramatically affect the resulting effect size, since d becomes artificially smaller as measurement error increases. Many psychological variables are measured with a substantial margin of error; thus, empirical values of d should be interpreted as lower bound estimates of the actual differences. Effect sizes that have been corrected for measurement error are explicitly flagged as such in the remainder of this article.

Regrettably, many researchers routinely interpret effect sizes as 'small,' 'moderate,' or 'large' based on the conventional cutoffs ($d = 0.20$, 0.50, and 0.80) originally proposed by Cohen (1988). This practice has little basis in statistical theory and is discouraged by most methodologists (Breaugh, 2003; Hedges, 2008; Vacha-Haase and Thompson, 2004). Ironically, Cohen himself advised against using his tentative cutoffs except as a last resort method for determining sample size in exploratory studies (Cohen, 1988). The substantive

Figure 1 Relation between effect size (d or D) and percent overlap between male and female distributions. The illustrative plots on the right show two univariate distributions overlapping by 10%, 30%, 50%, 70%, and 90% of their joint area. Overlap is computed assuming multivariate normality. See Del Giudice, M., 2009. On the real magnitude of psychological sex differences. Evolutionary Psychology 7, 264–279.

interpretation of an effect size may vary dramatically depending on measurement issues, theoretical considerations, and the scientific question being asked. For example, differences between group means have a progressively larger impact as one moves toward the distribution tails. Even when male and female distributions are largely overlapping in the region surrounding the mean of a trait, individuals with *extreme* values of the same trait may still be predominantly male or female. In the light of these considerations, debating whether males and females are 'more similar' or 'more different' based on a rigid interpretation of effect sizes (e.g., Hyde, 2005, 2013) is unlikely to prove a fruitful strategy for understanding the meaning of gender differences and their societal implications.

Univariate versus Multivariate Differences

The standard approach to gender differences in psychology is to measure groups of males and females on multiple variables – for example physical, verbal, and relational aggression – and compute an effect size for each individual variable. This approach becomes problematic in dealing with intrinsically multidimensional domains such as personality and aggression. To begin with, small differences in multiple traits can add up to a much larger effect if the traits are considered simultaneously. For example, facial features – nose length, eye size, face width, and so forth – show considerable overlap between genders when they are considered one by one. However, their *combined* effect results in nearly complete separation between male and female faces, and indeed, human observers can classify faces by gender with more than 95% accuracy (see Del Giudice, 2013). Another limitation of univariate effect sizes (such as d) is that they cannot take into account the patterns of *correlation* between the variables that constitute a given psychological domain.

The limitations of univariate effect sizes can be overcome by supplementing them with multivariate effect sizes that simultaneously consider multiple variables and their correlational structure. The natural extension of Cohen's d is the Mahalanobis D, a standardized difference between two groups in multivariate space. When employed to measure gender differences, D can be interpreted as the distance between group means on an abstract dimension of *masculinity–femininity* in the relevant domain. The interpretation of D in terms of distribution overlap is exactly the same as that of d (**Figure 1**). Unlike d, D is always positive since the concept of a higher or lower mean is meaningless in multidimensional space (Del Giudice, 2009). The application of multivariate effect sizes to gender differences has been debated by some authors (e.g., Hyde, 2013); however, the arguments leveled against D turn out to be either incorrect or logically inconsistent (Del Giudice, in press). In this article, both univariate and multivariate effect sizes are reported whenever the latter are available.

Dimensional versus Taxonic Differences

Finding evidence that, on average, males and females differ on a certain set of variables does not tell the whole story about the nature of gender differences in that domain. Another important question is whether gender differences are differences in *degree* – with males and females varying along a single continuum – or differences in *kind*, implying a clear-cut discontinuity in the distribution of variables between groups. This question is conceptually independent from questions about the *size* of those differences.

Taxometrics is a set of statistical methods that attempt to determine whether a certain group is a *taxon*, i.e., a clearly demarcated category that differs in kind and not just in degree from another group. In a recent paper, Carothers and Reis (2013) employed taxometrics to determine whether binary gender categories can be regarded as dimensional or taxonic in a number of domains including personality, social behavior, and sexuality. The results overwhelmingly supported a dimensional model of gender, with the exception of *sociosexuality* (the preference for promiscuous, uncommitted sex versus monogamous, committed partnerships). However, these pioneering findings must be taken with caution, since taxometric methods are unlikely to detect an existing taxonic structure if the mean difference between groups is smaller than about $d = 1.20$ (Beauchaine, 2007). Since the size of gender differences in many psychological traits falls below this threshold (see below), taxometric results are difficult to interpret with any confidence.

Gender Differences in Trait Variability

Males and females may differ not just in the mean value of a trait or behavior, but also in their *variability* around the mean. When such differences are found, the general tendency is for males to display more variability than females (Archer and Mehdikhani, 2003; Hyde, 2013). The more variable gender will tend to be overrepresented at both tails of the distribution, even if mean differences are small or absent (see Voracek et al., 2013). The standard metric for gender differences in variability is the variance ratio (VR), the ratio of male variance to female variance. $VR = 1$ indicates equality of variances, $VR > 1$ indicates higher variability in males, and $VR < 1$ indicates higher variability in females.

Gender Differences in Personality

Descriptive models of personality have a hierarchical structure, from broad and inclusive traits to narrow and specific ones. Typically, 3–6 broad traits ('domains' or 'global traits') are subdivided into 10–20 narrower traits ('aspects' or 'specific factors'); at the lowest level of description, dozens of specific personality 'facets' (usually 30–45) can be identified. Patterns of gender differences are already apparent at the level of broad traits, but become stronger and more recognizable at a finer-grained level of analysis.

Broad Personality Traits

Big Five Domains

The most widely adopted model of personality is the Five Factor Model (FFM), whose five domains are known as the Big Five: *neuroticism* (negative emotionality and emotional instability), *agreeableness* (altruism and cooperation), *conscientiousness* (self-control, self-discipline, and organization), *extraversion* (sociability, assertiveness, and positive emotionality), and *openness* (imagination, intellectual curiosity, and aesthetic appreciation). Across countries, gender differences in the Big

Five are largest in agreeableness ($d = -0.40$) and neuroticism ($d = -0.34$); females consistently score higher than males on both traits. Smaller differences favoring females are found in conscientiousness ($d = -0.09$) and extraversion ($d = -0.11$); finally, there are no reliable differences in openness ($d = 0.01$). There is some cross-cultural variability around these averages; as a rule, gender differences tend to be *larger* in individualistic, gender-egalitarian societies (Feingold, 1994; Lippa, 2010; Schmitt et al., 2008). In a reanalysis of a large US data set, Del Giudice (2009) found a multivariate difference of $D = 0.98$ (corrected) for the Big Five domains, corresponding to a 45% overlap between male and female distributions.

A recent study of variation in Big Five domains (Borkenau et al., 2013) found equal variance between genders in self-reported traits ($VR \approx 1$), but higher male variance in informant-reported traits ($VR \approx 1.20$). Neuroticism was an exception: males showed lower variability in self-reports ($VR = 0.89$) and equal variability in informant-reports ($VR = 1.01$). Given the comparatively small size of the study, these findings should be regarded as preliminary.

The Interpersonal Circumplex

In the interpersonal circumplex model (IPC), individual differences in personality are mapped on two independent axes of variation, *dominance* (assured-dominant versus insecure-submissive) and *nurturance* (warm-agreeable versus cold-hearted). The IPC can be regarded as an alternative representation of the extraversion and agreeableness domains of the FFM (DeYoung et al., 2013). The interpersonal dimensions of the IPC bring into sharp relief a pattern of gender differences that is partially masked by the structure of Big Five domains: on the traits that best correspond to those dimensions, males consistently score higher in dominance ($d \approx 0.20$–0.50) and lower in nurturance ($d \approx -0.25$ to -1.00; Costa et al., 2001; Del Giudice et al., 2012; Feingold, 1994). Based on data for dominance and warmth reported in Del Giudice et al. (2012), the multivariate effect size for the IPC can be estimated at $D = 1.14$ (corrected).

Temperament

In infants and children, individual differences in behavior are usually framed as 'temperament' rather than 'personality'; standard dimensions of temperament overlap only partially with adult personality traits. In a *meta-analysis* of temperament ratings from 3 months to 13 years of age, Else-Quest et al. (2006) found that females scored higher in all dimensions of *effortful control* (self-control and delay of gratification; $d = -0.05$ to -1.01), whereas males tended to score higher in dimensions of *surgency* (activity and sociability; $d = -0.11$ to 0.55). No reliable gender differences were observed in *negative affectivity* ($d = -0.17$ to 0.13), a surprising finding when contrasted with the robust gender differences in adult neuroticism. The mean variance ratios were $VR = 1.08$ for dimensions of effortful control, $VR = 1.03$ for dimensions of surgency, and $VR = 0.98$ for dimensions of negative affectivity.

Narrow Personality Traits

While broad traits such as the Big Five provide a compact description of individual differences, they are not necessarily the best level of analysis to investigate gender differences in personality. In many cases, the structure of broad traits masks the existence of lager gender differences at the level of narrower traits. For example, comparatively small differences in extraversion actually result from the combination of larger, opposite-sign differences in assertiveness–sensation seeking (higher in males) and sociability–gregariousness (higher in females). Weisberg et al. (2011) examined the 10 aspects of the Big Five and detected contrasting patterns of gender differences within extraversion ($d = -0.23$ for enthusiasm, $d = 0.09$ for assertiveness), conscientiousness ($d = -0.18$ for orderliness, $d = 0.06$ for industriousness), and openness ($d = -0.27$ for aesthetic openness, $d = 0.22$ for intellect). At the level of 30 personality facets, the *meta-analysis* by Costa et al. (2001) found differences of $d = -0.09$ to -0.44 for neuroticism facets, $d = -0.33$ to 0.38 for extraversion facets, $d = -0.35$ to 0.32 for openness facets, $d = -0.17$ to -0.43 for agreeableness facets, and $d = -0.13$ to 0.20 for conscientiousness facets.

The 15 primary factors (PF) of the 16 PF model are narrow personality traits roughly comparable to Big Five aspects. In a large US sample, Del Giudice et al. (2012) found differences ranging from $d = -2.29$ to 0.54 (corrected). The largest differences were in *sensitivity* (aesthetic, intuitive, and tender-minded versus utilitarian, objective, and tough-minded; $d = -2.29$), *warmth* ($d = -0.89$), *apprehension* (worried, insecure, and self-doubting versus secure and self-assured; $d = -0.60$), *dominance* ($d = 0.54$), and *emotional stability* ($d = 0.53$). The multivariate effect size for the 15 factors was $D = 2.71$ (corrected), corresponding to a 10% overlap between male and female distributions (Del Giudice et al., 2012).

Impulsivity, Risk-Taking, and Sensation Seeking

Impulsivity, risk-taking, and sensation seeking are a group of correlated traits that deserve special consideration in virtue of their social and clinical implications. In a *meta-analysis* of risk-taking that employed a broad definition of the term and a wide range of indicators – including for example 'smoking' and 'guessing' – Byrnes et al. (1999) found that overall levels of risk-taking were higher in males ($d = 0.13$). Cross et al. (2011) employed a narrower definition of risk-taking and found even stronger gender differences ($d = 0.37$ across methods). In the same *meta-analysis*, males also showed higher levels of sensation seeking ($d = 0.22$). Gender differences in impulsivity were considerably smaller ($d = 0.08$). This finding can be contrasted with the robust gender differences in effortful control (the reverse of impulsivity) found in studies of infant and child temperament. Males displayed more variability in risk-taking ($VR = 1.10$) and sensation seeking ($VR = 1.08$), but not in impulsivity ($VR = 1.00$). Gender differences in risk-taking are not limited to stable dispositions, but extend to the role of contextual factors in determining moment-to-moment attitudes toward risk. For example, several studies have shown that acute stress tends to increase risk-taking in males, but decrease it in females (Mather and Lighthall, 2012).

Summary

The typical personality profiles of males and females differ in a number of ways. On average, males are more dominant,

assertive, risk-prone, tough-minded, cold-hearted, emotionally stable, utilitarian, and open to abstract ideas. Females are more nurturant, warm, altruistic, submissive, risk-averse, tender-minded, emotionally unstable, and open to feelings and aesthetic experiences. These differences tend to be larger in more gender-egalitarian countries, and together define a global dimension of personality masculinity–femininity. The global overlap between adult men and women in the distribution of personality traits can be estimated at about 10% – close to that between male and female facial features (Del Giudice, 2013). In addition, men are somewhat more variable in most (but not all) dimensions of personality. Gender differences in temperament are already apparent in infancy and childhood, but correspond only in part to those in adult personality. In particular, early differences in impulsivity seem to dissipate in adults, while differences in negative emotionality emerge during development.

Gender Differences in Cooperation and Competition

Cooperation and competition are the basic polarities of social life; their constant interplay provides the background for the rich tapestry of human relationships. From childhood to adulthood, cooperation and competition outside the family occur with particular frequency and intensity between same-gender individuals (Benenson, 2013; Geary, 2010; Geary et al., 2003). Both one's closest friends and allies and one's fiercest adversaries are likely to be other individuals of the same gender. The dynamics of same-gender relations are an essential aspect of human social behavior, and tend to carry over into mixed-gender interactions.

Cooperation and Competition in Males

While both genders participate in many kinds of social interactions, ranging from dyadic friendships to large groups, large-scale cooperation is a distinctive attribute of male sociality across the life span. Males are more likely to engage in cooperative group activities, form larger groups than females, and engage in frequent and intense between-group competition against other male groups. Male groups are characterized by stable internal hierarchies of status and dominance; within groups, competition tends to be individualistic or one-on-one (Benenson, 2013; Geary, 2010; Geary et al., 2003). A *meta-analysis* of cooperation in experimental games played between strangers (Balliet et al., 2011) showed that male–male interactions tend to be more cooperative than female–female interactions ($d = 0.16$). At the same time, males tend to show less altruistic and prosocial behavior across a range of domains, from sharing possessions to organ donations (Ellis et al., 2008). This is consistent with males' lower levels of agreeableness and nurturance (see above); the main exception to this pattern is 'heroic' helping behavior, especially when directed toward women (Eagly and Crowley, 1986). In group settings – including mixed gender groups – males display higher levels of task-oriented behavior and lower levels of social-emotional behavior ($d = 0.59$ and -0.59 in the *meta-analysis* by Carli, 1982).

Cooperation and Competition in Females

The dynamics of cooperation and competition in females are more complex and nuanced than their male counterparts. Female friendship tends to be more complex and less focused on shared activities than male friendships. Starting from middle childhood, females are more likely to form dyadic relationships characterized by high levels of intimacy, emotional support, exclusivity, and reciprocity. In turn, dyads are embedded in larger social networks in which hierarchies tend to be more fluid than those of male groups (Ellis et al., 2008; Geary, 2010; Geary et al., 2003). Peer relations in females are strongly influenced by norms of caring and equality. Superiority and overt competition are discouraged, and – unlike in male groups – high-status peers are often the target of dislike and denigration. Accordingly, female competition is often indirect and balanced by egalitarian concerns; displays of overt competitiveness are usually restricted to high-status females (Benenson, 2013). In group settings, females display higher levels of social emotional behavior focused on maintaining and managing personal relationships ($d = -0.59$ in Carli, 1982). This pattern is consistent with females' higher levels of agreeableness and nurturance and lower levels of dominance and assertiveness (see above). A prominent feature of female social relationships is social exclusion, an indirect aggression tactic in which a target individual is ostracized by the others. Both threats of social exclusion and actual episodes of ostracism are more common in female groups, especially in childhood and adolescence (Benenson, 2013).

Aggression

The existence of gender differences in aggression is one of oldest and most robust findings in this area. In psychology, the standard distinction is that between *physical*, *verbal*, and *indirect* (or *relational*) forms of aggression. Indirect aggression is used to damage another individual's social standing by ostracizing, gossiping, spreading malicious rumors, and so forth. In a comprehensive *meta-analysis*, Archer (2009) found that, across age groups, males engage in more direct aggression, both physical ($d = 0.58$) and verbal ($d = 0.29$), while females tend to engage in more indirect aggression ($d = -0.16$). A *meta-analysis* of studies of children and adolescents (Card et al., 2008) showed similar results for physical and verbal aggression ($d = 0.73$ and 0.38, respectively), and a smaller effect for indirect aggression ($d = -0.06$). Gender differences in aggression – especially physical aggression – peak between adolescence and young adulthood (Archer, 2009). Overall, the multivariate effect size for male versus female patterns of aggression can be estimated at about $D = 0.89$–1.01 (corrected; Del Giudice, 2009).

While males and females tend to display similar levels of indirect aggression (especially compared with the much larger difference in physical aggression), the finer-grained dynamics of aggressive behavior differ between male and female groups. In particular, attractive females are the target of *more* indirect aggression by other females, whereas attractive males tend to receive *less* indirect aggression from their peers

(Vaillancourt, 2013). Also, experimental studies show that males tend to engage in *unprovoked* aggression more frequently than females ($d = 0.33$; Bettencourt and Miller, 1996).

Social Play

Social play is a universal feature of human development, and – like many other social activities – involves a complex balance of cooperation and competition. Gender differences in social play can be summarized as follows. Across cultures, girls engage more frequently in cooperative, nonaggressive social play, whereas boys show a higher frequency of play fighting and 'rough-and-tumble' play (about 3–6 times as much as girls; Geary, 2010), as well as higher levels of between-group competition. Both genders engage in sociodramatic play, in which social episodes are enacted based on everyday or fantastic themes. However, boys' themes more frequently involve power, dominance, and aggression, whereas girls' themes tend to involve interpersonal and family relationships (including play parenting). Gender differences in play behavior peak in middle childhood, around 8–10 years of age (Ellis et al., 2008; Geary, 2010).

Summary

Males tend to form larger, activity-oriented, competitive groups in which hierarchies tend to be stable and individual relationships require comparatively little emotional investment. Competition often involves direct forms of aggression. Intimate, high-intensity dyadic relationships play a bigger role in female social networks. Female groups are more emotion-focused and are characterized by unstable hierarchies and strong egalitarian norms; competition is often indirect and less openly confrontational. Aggression shows robust patterns of gender differences. Direct aggression – especially physical aggression – is higher in males; indirect forms of aggression are higher in females, though the size of the effect is considerably smaller. Gender differences in play behavior peak in middle childhood and mirror the broader pattern of gendered social dynamics: males engage in more play fighting and between-group competition, while females engage in more cooperative play centered around relational themes.

Gender Differences in Communication

Social behavior would be all but impossible without communication. In humans, the interplay between language and nonverbal behavior forms the background for an exceedingly complex communication system. Research on gender differences in linguistic communication has focused mainly on verbal ability (e.g., vocabulary, reading ability), language use (e.g., assertive communication), and conversational style (e.g., interruptions). Gender differences in nonverbal communication have been extensively studied, and include both the production of nonverbal displays – such as gestures and facial expressions – and the ability to accurately decode other people's nonverbal behavior.

Verbal Ability

In a classic meta-analysis, Hyde and Linn (1988) found a female advantage in general verbal ability ($d = -0.20$). Specific abilities showed a more nuanced pattern of results: females performed better on measures of speech production ($d = -0.33$) and anagram solving ($d = -0.22$); smaller differences were found in writing and reading ($d = -0.09$ and -0.03, respectively), while males showed an advantage in verbal analogies ($d = 0.16$). No reliable gender differences were detected in vocabulary skills ($d = -0.02$). The size of gender differences was largely independent of age, and showed no clear developmental trend from childhood to adulthood.

Language Use and Conversational Style

Given the robust gender differences observed in dominance- and nurturance-related dimensions of personality (see above), it is reasonable to expect males and females to differ in their typical patterns of language use and conversational style. Indeed, *meta-analytic* data in both children and adults show that, averaging across contexts, males tend to use more assertive speech ($d \approx 0.10$) whereas females tend to use more affiliative speech ($d \approx -0.10$). In addition, girls are more talkative than boys ($d = -0.11$), but the difference is reversed in adults ($d = 0.14$; Leaper and Ayres, 2007; Leaper and Smith, 2004). A related finding (Leaper and Robnett, 2011) is that females use more tentative speech, including more tag questions, e.g., "isn't it?" ($d = -0.23$) and hedges, e.g., "I think" ($d = -0.15$). A conspicuous aspect of gender differences in language use is their strong dependence on contextual factors such as group size, age and gender of conversation partners, and familiarity. Depending on the specifics of the conversational setting, these differences can easily increase, decrease, or even change sign (Leaper and Ayres, 2007; Leaper and Smith, 2004). On average, males interrupt their conversation partners more than females do ($d = 0.15$); gender differences are especially large in the use of *intrusive* interruptions ($d = 0.33$), which can be unambiguously interpreted as a form of dominant behavior (Anderson and Leaper, 1998).

Nonverbal Communication

Nonverbal Behavior

A consistent finding in nonverbal behavior research is that females are generally more expressive than males. A *meta-analysis* by Hall (1984) found an overall effect size $d = -1.01$ for facial expressiveness and $d = -0.58$ for bodily expressiveness, even if males tend to adopt more expansive, open postures ($d = 1.04$). Females are also better at deliberately expressing emotions ($d = -0.52$). Gender differences in expressiveness show a clear developmental trend from childhood to adulthood (Chaplin and Aldao, 2013). In children, a smaller female advantage is found on positive emotions ($d \approx -0.08$) and *internalizing* negative emotions such as sadness and anxiety ($d \approx -0.10$); at the same time, boys tend to be more expressive on *externalizing* negative emotions such as anger ($d \approx 0.09$). By adolescence, however, females become more expressive across the board

and effect sizes increase ($d \approx -0.35$ for negative emotions and -0.28 for positive emotions).

Smiling and crying are two prototypical manifestations of expressive behavior. A *meta-analysis* of smiling from adolescence to adulthood showed that females tend to smile more frequently across contexts and cultures ($d = -0.41$). Average differences peak in adolescence ($d = -0.56$) and decrease with age ($d = -0.11$ in seniors); also, effect sizes are especially large in North American countries (LaFrance et al., 2003). As with language use, gender differences in smiling are highly contingent on contextual factors; for example, males and females differ more when they believe they are being observed than when they believe they are alone ($d = -0.46$ vs -0.19). Gender differences in crying are larger and more robust than those in smiling. Across cultures, females show a stronger tendency to cry ($d = -1.11$) and cry more often than males do ($d = -0.94$). Also, gender differences in crying tend to be *larger* in more individualistic, gender-egalitarian countries (van Hemert et al., 2011).

Nonverbal Decoding

In addition to being more expressive, females are generally better at processing and decoding other people's nonverbal behavior. In her *meta-analysis*, Hall (1984) found an overall effect size $d = -0.43$ for nonverbal decoding skills across communicative modalities. The female advantage in processing facial expressions tends to be smaller in childhood and adolescence ($d \approx -0.20$; McClure, 2000). There is some evidence that gender differences in expression processing may peak in infancy, decrease in early childhood, then peak again in middle childhood (McClure, 2000).

Summary

Females enjoy a general advantage in communication skills, both in the verbal domain (with the exception of verbal analogies) and in the production and decoding of nonverbal displays. The higher expressiveness of females is reflected in a higher frequency of both smiling and crying; gender differences in crying are especially robust, and tend to increase in more gender-egalitarian countries. Consistent with the data on personality and social relations, males tend to use more assertive speech and interrupt their conversation partners more often, while females tend to use more affiliative and tentative speech. However, gender differences in language use are highly dependent on contextual factors, testifying to the remarkable strategic flexibility of human communication.

Abstract

This article examines the contribution of economics to the analysis of gender differences in behavior and economic outcomes, including labor supply and the allocation of time; the gender division of labor in the family; analyses of gender differences in wages and occupations, including the human capital explanation and models of discrimination; as well as considerations of the gender pay gap in the context of the overall structure of wages.

Gender and the Economics of Gender

This article describes the relationship of gender to economics, focusing on economic analyses of gender differences in behavior and economic outcomes. Historically, gender has not been perceived to be a central concept in economic analysis. However, as the force of current events has thrust gender-related issues to the fore, economists have responded. The outcome has been not only a better understanding of the nature and causes of gender differences, but also an enrichment of the discipline itself.

One reason for the historical neglect of gender issues by economists is that economists traditionally focused on market transactions and, traditionally, most married women were primarily engaged in nonmarket activities. As women have come to comprise a larger share of the paid labor force and as market work has loomed larger in the typical woman's life, interest in the determinants of gender differences in behavior and labor market outcomes has grown. At the same time, the growing interest of economists in analyzing nonmarket work and demographic outcomes such as marriage, divorce, and fertility also played an important role in increasing economists' attention to gender-related issues.

Time Allocation in the Family Context

The traditional theory of labor supply is a simple extension of consumer theory. Individuals maximize their utility, which is derived from market goods and leisure, subject to budget and time constraints. The labor supply decision is determined by the opportunity wage (the wage rate the individual could earn in the labor market), nonlabor income (the amount of income available to them from other sources), and the individual's tastes or preferences for work vs. leisure. While this theory is sufficient for many purposes, it has substantial limitations for understanding the determinants of the gender division of labor in the family and the factors influencing women's labor force participation. The key to addressing these issues is a fuller understanding and analysis of the household production process. Prompted in part by their desire to understand the causes of the rising labor force participation of married women in the post–World War II period, economists extended the traditional theory of labor supply to consider household production.

Household Production and the Allocation of Time

The work of Becker and Mincer in the 1960s was particularly influential in bringing the analysis of household production into the mainstream. In analyzing married women's labor force participation in the US, Mincer (1962) pointed to the importance for women of the three-way decision among market work, nonmarket work, and leisure. He attributed the growth in married women's participation during the early postwar period to women's rising real wages which induced them to substitute market work for housework. This response was large enough to more than offset the negative income effect on their labor supply associated with the growth in their husbands' real wages.

Becker (1965) advanced this process further by proposing a general theory of the allocation of time. In this and other work (summarized in Becker, 1981), he laid the foundations for the 'new home economics', including economic analyses of time allocation, marriage, divorce, and fertility. Interestingly, while Mincer opened a window on household production by distinguishing nonmarket work from leisure, Becker was able to provide a further advance by again eliminating the distinction. However, while in the traditional labor supply model all nonmarket time is spent in leisure, in Becker's model all nonmarket time is spent in household production. Becker assumes that households derive utility from 'commodities' that are produced by inputs of market goods and nonmarket time.

Consider the relationship between children and women's labor force participation. Young children may be viewed as a 'time-intensive' commodity. Traditionally, the mother has been the primary care giver. While it is possible to substitute market goods and services (e.g., babysitters, day care centers) for home time in caring for children, these alternative production techniques tend to be costly and may be difficult to implement. Thus, at any point in time, the probability that a woman will participate in the labor force is expected to be inversely related to the number of children present. Over time, the increase in women's labor force participation rates has been associated with decreasing birthrates, as well as increases in the availability of alternative child care arrangements.

The Determinants of Tastes for Market Work

While economists have generally not examined the determinants of tastes for market work, this is an increasing focus of

research. Perhaps not surprisingly, the evidence suggests that family background influences such tastes. For example, mother's labor supply behavior has been found to be positively associated with their daughter's labor force participation decision and also to have a positive association with the labor force participation of their son's wife (Farré and Vella, 2013; Fernández et al., 2004).

Culture also plays a role. For example, it has been found that women migrating to the US from countries with relatively high female labor force participation rates have persistently higher labor supply in the US than women coming from countries with lower female participation rates (Blau et al., 2011). Similarly, the labor supply behavior of the US-born daughters of immigrants (the second generation) has been found to be positively associated with both female participation rates in their parents' country of origin (Fernández and Fogli, 2009) and the participation patterns in the US of immigrants from those origin countries in the parents' generation (Blau et al., 2013).

Economic Development and Trends in Labor Supply

Labor force participation is important for women because it is associated with female empowerment in the family and in the broader society. The relationship between women's labor force participation and economic development has been found to follow a U-shaped pattern (Goldin, 1990, 1995). Female labor force participation is high at earlier stages of economic development, when women tend to be heavily involved as family workers (often unpaid) on the farm or in family businesses, or otherwise working for pay or producing for the market within the household. Their labor force participation initially falls in the course of economic development, as the locus of production moves out of the household and family enterprises and into factories and offices. Goldin argues there is a stigma against wives doing wage work in manufacturing and agriculture that contributes to reducing women's participation at this stage. As women's education levels rise and their job opportunities become more attractive, the stigma against married women working is diminished and female labor force participation increases.

Goldin (1990) shows that, in the US, these shifts in participation patterns were accompanied by changes in the elasticity (responsiveness) of women to their wages and nonlabor incomes (generally husbands' income). Around the turn of the twentieth century (toward the bottom of the U), married women's wage elasticity (responsiveness to their own wages) was very small, but the elasticity associated with their husbands' income was negative and very large in absolute value. That is, women worked primarily if their husband's income was inadequate. As development proceeded (along the rising portion of the U), women's labor supply decisions became more responsive to their own wages and labor market opportunities and less responsive to (determined by) their husband's income. Goldin (1990) predicted that, as divorce rates rose and women's jobs increasingly became careers as opposed to merely a means to earn income, not only should wives' responsiveness to husbands' income continue to decline, but also should their responsive to their own wages. That is, as women became more firmly attached to the labor force, like men, they would be less likely to change their labor supply in response to changes in their wages or nonlabor (husbands') income. Consistent with this, Blau and Kahn (2007) found that, in the US, women's wage and income elasticities were each cut roughly in half between 1980 and 2000 (although they still remain higher than the corresponding male elasticities). Another indicator that women have become more firmly attached to the labor force is that most studies for the US find that the negative effect of children on women's labor force participation has diminished over time (e.g., Macunovich, 2010).

Although female labor force participation has risen in most countries, there are, nonetheless, substantial differences even among the economically advanced countries. These differences are due to a variety of factors ranging from religion and culture to economic organization to government policies. Some evidence suggesting a potentially important role for government policy is suggested by international comparisons of the impact of family-friendly policies; this research also shed light on recent developments in the US.

After a half century of strong growth after World War II, US female labor force participation rates began to stagnate in the mid-1990s. In 1990, the United States had one of the higher female participation rates among economically advanced countries – it ranked sixth out of a set of 22 OECD countries in that year. By 2010, however, as other nations caught up to and surpassed the US, the US ranked 17th (Blau and Kahn, 2013). One major difference between the US and other OECD countries is that most offer more generous parental leave programs (both in length of the leave and benefits received) and many require employers to provide greater part-time options. Blau and Kahn (2013) find that the greater expansion of these family-friendly policies in other OECD countries accounts for a substantial portion (nearly 30%) of the decrease in US women's labor force participation rates relative to these other countries between 1990 and 2010. These results suggest a positive employment effect for such policies and also that work–family issues are a factor in the US stagnation in participation rates.

While more expansive family-friendly policies may promote women's labor force participation, they come at the risk of channeling women into 'mommy track' jobs that tend to be associated with fewer opportunities for advancement and lower pay. Blau and Kahn (2013) report that US women were more likely than women in these other countries to have full-time jobs and to work as managers or professionals. These results are consistent with the negative wage effects of longer leave entitlements (over 26 weeks) reported by Ruhm (1998). Thus there may be a trade-off between some policies that make it easier for women to combine work and family and women's advancement at work.

The Gender Division of Labor

In the discussion of the allocation of time earlier, it was simply assumed that women tend to bear the primary responsibility for childcare and housework. However, the gender division of labor in the family is also an issue that the new home economics addresses. According to Becker (1981), the division of labor will be dictated by comparative advantage. To the

extent that women have a comparative advantage in household and men in market production, it will be efficient for women to specialize at least to some extent in the former while men specialize in the latter. In Becker's view, the increased output resulting from this arrangement maximizes family utility and constitutes one of the primary economic benefits to marriage. Thus, women's rising labor force participation is expected to reduce the gains from marriage, thereby contributing to higher divorce and lower marriage rates. However, offsetting this expectation, at least to some extent is that, as Stevenson and Wolfers (2007) and others have pointed out, with the growth of the two-earner family, marriages may be increasingly based on complementarity between the spouses (enjoyment of time spent together and joint consumption), rather than on substitution between them (a gender-based division of labor). Moreover, the benefits to complementarity may be increasing as employed spouses share more common interests.

Economists have also turned their attention to better understanding family decision making. Led by Manser and Brown (1980) and McElroy and Horney (1981), there has been a growing application of bargaining models to family decision making, These models assume that the preferences of husbands and wives may diverge and that outcomes for each spouse can be modeled using game theory. In the most popular application of these models to the family, the cooperative bargaining model of marriage, the utility received by each spouse in the Nash bargaining solution is positively related to the utility of each partner at the 'threat point', most commonly taken to be the utility that each would receive if the marriage irretrievably broke down. This suggests that a woman who works outside the home will have a higher utility at the threat point and hence a more favorable distribution within marriage. Studies reviewed by Lundberg and Pollak (1996) provide empirical support for this model in their finding that earned or unearned income received by the wife has a different effect on demand patterns than income received by the husband. Moreover, it has generally been found that when women have greater control over household resources, spending patterns are changed in ways that benefit children. In developing countries, where resources are especially scarce, such a reallocation can be quite important for child health and well-being.

Gender Differences in Labor Market Outcomes

Women earn less than men, on average, in all advanced economies, though the extent of the gender pay gap varies considerably across countries and has been declining in many of them in recent years (e.g., Blau et al., 2014). There is also considerable employment segregation of men and women – by occupation, industry, and firm. Segregation of men and women by occupation, for which summary data are most readily available, has been found to be prevalent in all economically advanced countries, though it too has been declining in recent decades in most OECD countries, including the US (e.g., Blau et al., 2014).

There are two broad approaches to analyzing gender differences in labor market outcomes. First is the human capital explanation which lays primary emphasis on men's and women's own choices in explaining occupation and pay differences. Second are a variety of models of labor market discrimination which place the onus for unequal outcomes on differential treatment of equally qualified men and women in the labor market. Some advances have also been made by considering the gender pay gap and other demographic differentials in the context of the overall structure of wages.

The Human Capital Explanation and Other Supply-Side Sources

The human capital explanation for gender differences in occupations and earnings, developed by Mincer and Polachek (1974) and others, provides an explanation for gender differences in market outcomes on the basis of the traditional division of labor by gender in the family. Anticipating shorter and more discontinuous work lives as a consequence of their family responsibilities, women have lower incentives to invest in on-the-job training than men. Their resulting smaller human capital investments will lower their relative earnings. Women are also expected to choose occupations for which human capital investments are less important and in which the skill depreciation that occurs during time spent out of the labor force is minimized. They will avoid especially jobs requiring large investments in firm-specific skills (i.e., skills which are unique to a particular enterprise), because the returns to such investments are reaped only as long as one remains with a particular employer. At the same time, employers are expected to be reluctant to hire women for such jobs because they bear some of the costs of firm-specific training (see the discussion of statistical discrimination below).

There also appears to be a motherhood wage penalty in many advanced countries, that is, lower earnings for women who are mothers, all else equal (Sigle-Rushton and Waldfogel, 2007). This likely reflects the loss of their tie to the firm and associated firm-specific skills when women withdraw from the labor force upon the birth of a child. Some evidence (e.g., Waldfogel, 1998) suggests that provision of parental leaves may reduce the size of the family penalty by maintaining the tie to the firm, although, as our previous discussion suggests, extended leaves may have a negative effect on women's wages, so the length of the leave is likely important.

The human capital model suggests not only that women should be less likely than men to invest in on-the-job training but also that they will be reluctant to make large investments in formal education, again because they do not expect to be in the labor force long enough to reap sufficient returns on their investment. However, although, traditionally, men were more likely to go to college than women, in the US and other economically advanced countries, women have not only caught up to men in college graduation rates but have now surpassed them.

Women's increasing labor force attachment is undoubtedly one factor contributing to their increased incentives to invest in higher education. However, that does not explain why they have surpassed men in most countries. One reason for this appears to be that girls and young women have lower non-pecuniary costs of investing in education than boys and young men – that is, investing in education appears to entail more disutility for males due to their slower social development and more serious behavioral problems (Goldin et al., 2006).

In recent years, labor economists have become increasingly interested in the effect of noncognitive or 'soft' skills – including psychological attributes, preferences, and personality – on labor market outcomes and behavior (Heckman and Kautz, 2012). With respect to gender, intriguing findings suggest a number of psychological attributes that differ between women and men. For example, women have been found to be less willing than men to negotiate and compete and to be more risk averse (for reviews, see Bertrand, 2010; Croson and Gneezy, 2009). Such differences in attitudes could help to explain the observed gender differences in pay and occupations. This line of work is relatively new in economics and, while of considerable interest, the sources of the observed gender differences (e.g., nature vs. nurture), as well as their consequences for labor market outcomes are not fully known, particularly since much of the evidence on gender differences in psychological attributes has been gleaned from laboratory experiments. Moreover, it is important to bear in mind that gender differences in all psychological attributes do not necessarily favor men. As we have seen, the greater behavioral problems of boys and young men appear to contribute to male's lower rate of college going. It will be interesting to learn more about the contribution of psychological factors to gender gaps as we accumulate more evidence, including from field experiments.

Models of Labor Market Discrimination

To the extent that gender differences in outcomes are not fully accounted for by productivity differences due to gender differences in human capital and other supply-side sources, models of labor market discrimination offer an explanation. Theoretical work in this area was initiated by Becker's (1957) model of racial discrimination. Becker conceptualized discrimination as a taste and analyzed three cases, those in which the discriminatory tastes were held by employers, co-workers, and customers or clients. Under certain circumstances, such discrimination will cause a wage differential between men and women. Discriminatory employers will only hire women at a sufficient wage discount that compensates them for the disutility of employing women. Discriminatory male workers will demand a wage premium to work with women thus raising men's relative wages, and the reluctance of discriminatory customers or clients to buy goods or services provided by women will make women less productive in terms of revenue brought in, thus depressing women's relative wages.

Models based on tastes for discrimination are also consistent with employment segregation, but do not necessarily predict it will occur. If wages are flexible, it is altogether possible that discrimination will result in lower pay for women, but produce little or no segregation. However, if discriminatory tastes against women in traditionally male pursuits are both strong and prevalent, women may tend to be excluded from these areas. If such segregation does occur, it may or may not be associated with gender pay differentials. In the presence of sufficient employment opportunities in the female sector, equally qualified women may earn no less than men. The relationship between occupational segregation and earnings differentials is clarified in Bergmann's (1974) overcrowding model. If potentially equally qualified men and women are segregated by occupation, the wages in male and female jobs will be determined separately by the supply and demand for labor in each sector. Workers in male jobs will enjoy a relative wage advantage if the supply of labor is more abundant relative to demand for female than for male occupations.

One question that has been raised about the Becker model is how employer discrimination can persist in the long run in the face of competitive forces. The least discriminatory firms, which hire more lower-priced female labor, would have lower costs of production. In the long run, they should expand and drive the more discriminatory firms out of business. One answer, suggested initially by Becker himself, is that discrimination will be located in sectors of the economy that are not competitive. While Becker emphasized monopolistic elements in the product market, a related approach targets monopsonistic power on the part of the employer in the labor market (e.g., Madden, 1973; Black, 1995).

In addition, models of statistical discrimination were later developed, in part to explain the persistence of discrimination in the long run in the face of competitive forces. Such models assume a world of uncertainty and imperfect information; thus differences between groups in the expected value of productivity or in the reliability with which productivity may be predicted are expected to result in differences in the treatment of members of each group. So, for example, employers may believe that women are more likely to quit their jobs than men with similar observed characteristics (education, experience, etc.) or they may believe that women's turnover can be less reliably predicted by their measured characteristics than men's. As a consequence, they may pay women less, exclude them from jobs requiring substantial firm-specific training, or deny them promotions.

It has been argued that such statistical discrimination (making decisions on the basis of the average characteristics of the group) is consistent with profit maximization and can thus persist in the face of competitive forces. However, Aigner and Cain (1977) contend that such models are no more convincing in explaining the persistence of discrimination than models based on tastes. To the extent that employers' views are correct, the lower expected productivity of women will reduce their wages but women as a group will be paid their expected productivity. This does not constitute labor market discrimination as economists define it, that is, pay differences that are not accounted for by productivity differences. Moreover, they note that when employer beliefs regarding average differences are erroneous, discrimination clearly exists but in their view discrimination based on such misperceptions is even less likely to persist in the long run than discrimination based on tastes. Finally, though they acknowledge that less reliable predictions of a group's productivity combined with risk aversion by employers could produce a discriminatory differential, a perfectly elastic supply of risk neutral entrepreneurs would be expected to erode discriminatory differentials based on this factor.

However, such models may have greater usefulness in explaining the persistence of gender differentials in pay than Aigner and Cain's analysis suggest. Consider first the situation

where employer perceptions are correct, is it appropriate to consider this a form of 'discrimination' in any sense? From a normative perspective, the answer may be yes, to the extent that basing employment decisions on a characteristic like sex – a characteristic that the individual cannot change – could be viewed as inequitable. Indeed, the practice of judging an individual on the basis of group characteristics rather than upon his or her own merits seems the very essence of stereotyping or discrimination. Such behavior is certainly not legal, for example, under antidiscrimination laws and regulations.

Now consider the situation where employer perceptions are incorrect. If statistical discrimination is accompanied by feedback effects, this may be a credible source of persistent discriminatory pay differences. For example, if employers incorrectly expect that women are more likely to quit their jobs, they may respond by giving women less firm-specific training or assigning them to dead-end jobs. Faced with few incentives to remain on the job, women may respond by exhibiting exactly the higher turnover that employers expect.

This criticism of the Becker model – its inability to explain the persistence of discrimination against women in the long run – has proved to be a double-edged sword in that it has led some economists to doubt that labor market discrimination is responsible, in whole or part, for observed gender differences in labor market outcomes. Yet it is important to recognize that discrimination is an intrinsically complex process. Thus, it is not surprising that no simple solution has been found to the question of why discrimination may persist in the face of competitive forces. Similarly, the various models of discrimination, each emphasizing different motivations and different sources of this behavior, need not be viewed as alternatives. Rather, each may serve to illuminate different aspects of this complex reality. Moreover, as gender discrimination has become less socially acceptable, it has likely become less overt and more subtle. Indeed, there is growing evidence from social psychologists that discriminatory attitudes and stereotyping may even be unconscious (e.g., Fiske, 1998; Bertrand et al., 2005). Finally, as our discussion earlier suggests, discrimination can adversely affect women's human capital investments and labor force attachment by lowering the market rewards to this behavior (e.g., Weiss and Gronau, 1981).

Evidence on Human Capital, Discrimination, and the Gender Pay Gap

The typical approach to analyzing the sources of the gender pay gap is to estimate wage regressions specifying the relationship between wages and productivity-related characteristics for men and women. The gender pay gap may then be decomposed statistically into two components: the first, due to gender differences in measured characteristics and the second, which is 'unexplained' and potentially due to discrimination.

Such studies provide considerable empirical support for both gender differences in human capital and other measured characteristics and labor market discrimination in explaining the gender pay gap (for a review, see Hersch, 2006). For example, Blau and Kahn (2006) report that, in 1998, for a sample of full-time workers, US women's wages were 80% of men's, on average. Adjusting for gender differences in human capital (i.e., education and experience) raises the ratio to 81%, while additionally adjusting for gender differences in industry, occupation, and unionism further increases it to 91%. Thus, while measured characteristics, particularly industry and occupation, are important, women still earn considerably less than similar men, even when all measured characteristics are taken into account. (Interestingly, these findings imply that human capital factors taken together do not explain much of the gender difference in pay. This is because although women had less labor market experience than men, on average, which does help to account for the gender difference, they had *higher* levels of education, which works in the opposite direction.)

One problem with studies of this type is that discrimination may be overestimated to the extent that unexplained pay differentials between men and women are due in whole or part to gender differences in unmeasured qualifications. On the other hand, to the extent that unmeasured factors favor women or that the regression models include controls for characteristics like industry or occupation that could themselves be due to discrimination, discrimination may be underestimated.

Studies that use an experimental design provide additional evidence of discrimination that addresses concerns regarding unmeasured characteristics. For example, Neumark et al. (1996) analyzed the results of a hiring 'audit' in which male and female pseudo-job seekers were given similar résumés and sent to apply for waiter or waitress jobs at the same set of Philadelphia restaurants. The results provided statistically significant evidence of discrimination against women in high-priced restaurants where earnings of workers are generally higher. A second study, Goldin and Rouse (2000), examined the impact of the adoption of 'blind' auditions by symphony orchestras in which a screen is used to conceal the identity of the candidate. Using data from actual auditions, they found that the screen substantially increased the probability that a woman would advance out of preliminary rounds and be the winner in the final round. Finally, there is evidence that suggests women, but not men, face discrimination based on their parental status. Based on both laboratory and field experiments, Correll et al. (2007) found that study participants had less favorable views regarding the résumés of equally qualified mothers relative to those of nonmothers, while fathers were not disadvantaged relative to nonfathers.

The Role of Wage Structure

Work by Juhn et al. (1991) on trends in the race pay gap over time in the US has highlighted an additional factor, overall wage structure, which is also relevant to analyzing the gender pay gap. Wage structure is the array of prices determined for labor market skills and the rewards to employment in particular sectors. Since men and women tend to have different levels of labor market qualifications (especially work experience) and to be employed in different occupations and industries, the returns to skills and the size of premiums for employment in predominantly male sectors may impact the gender pay gap. All else equal, the larger the returns to skills like experience and the larger the rewards to employment in predominantly male

occupations and industries, the larger will be the gender pay gap.

Blau and Kahn (1996) have applied this insight to understanding international differences in the gender pay gap in order to address a paradox. The relative qualifications of American women are high compared to women in other countries, and the US has had a longer and often stronger commitment to antidiscrimination laws than most economically advanced nations. Yet the US has traditionally been among the countries with the largest gender pay gaps. The resolution to this paradox lies in the decentralized system of wage setting in the US that has resulted in a highly dispersed wage distribution and high returns to labor market skills and employment in particular sectors. In contrast, the greater role of unions and government in the labor markets of other economically advanced nations has resulted in higher wage floors and more compressed wage distributions from which employed women, as a relatively low-wage group, disproportionately benefit.

This raises the question of how, given the rising wage inequality that has occurred in many of the advanced industrialized countries, women have nonetheless been able to narrow the wage gap with men in many cases. Results for the US from Blau and Kahn (2006) suggest that women have been able to compensate for the adverse effects of rising inequality and higher rewards to skills by improving their relative qualifications, particularly their average work experience and their occupational distribution. In addition, the unexplained portion of the pay gap declined, reflecting an upgrading of women's unmeasured labor market skills, a decline in discrimination against women, and/or broader economy-wide shifts in the demand for labor favoring the types of occupations and industries in which women tend to be employed (for more on demand, see also, e.g., Welch, 2000; Bacolod and Blum, 2010).

Of course, international differences in the gender wage gap and changes over the time in the gap are affected by a variety of other factors, in addition to wage structure. One that is interesting to consider is selection: which women choose to participate in the labor force. So, for example, in Southern European countries, where female participation rates are quite low, gender wage gaps also tend to be relatively low. Olivetti and Petrongolo (2008) suggest that the reason for these relatively low gender gaps is that in these countries where market work is uncommon for women, it is concentrated among women who can earn especially high wages when they enter the labor market. This lowers the measured gender wage gap. In countries with higher participation rates, on the other hand, more low-wage women are included in the labor force and the measured gender wage gap is larger. Such composition issues have also been examined in the context of explaining the trends in the gender wage gap in the US, with Blau and Kahn (2006) assigning such compositional shifts a relatively modest role and Mulligan and Rubinstein (2008) according them more importance.

Conclusion

This review suggests that women's economic roles in the family and their labor market outcomes are closely related. This has undoubtedly played a role in the persistence of gender differences in both spheres. However, increasing opportunities for women in the labor market may be expected to reduce gender differences in family roles, while such a diminution of adherence to the traditional division of labor in the family is likely to enhance women's position in the labor market further. Thus, just as a fuller understanding of the interrelationships between women's roles in the family and their status in the labor market helps us to understand the persistence of gender inequality in economic outcomes, it also enables us to appreciate how changes in either one of these spheres, or both, can induce a mutually reinforcing process of change. Reductions in the pay gap in many of the economically advanced countries may well signal the operation of such a process.

Gender, Feminism, and Sexuality in Archaeological Studies

Ericka Engelstad, Institute of Archaeology and Social Anthropology, University of Tromsø, Tromsø, Norway

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Gender archaeology combines critical studies of the ways in which archaeological knowledge of gender, sex, and sexuality is produced, presented, and represented. Traditional archaeology was concerned with artifacts, cultures, societies, and people in both prehistory and history. An increasing interest in people in the past revealed that archaeologists were mostly concerned with men – man the hunter and warrior, and little concerned with women and gender. The 1980s saw the beginning of gender archaeology in Norway and the United States. Since then, there has been an increasing interest in gender archaeology and numerous studies of how gender varied over time as seen in studies of social relations in a wide range of ancient societies, variation in making and using tools, technological innovations, settlements, and ways of living.

Gender archaeology combines critical studies of the ways in which archaeological knowledge of gender, sex, and sexuality is produced, presented, and represented. Feminist/gender studies in archaeology started with critiques of the overdetermination of women's lives by nature or biology both in the past and present, thereby reducing multifaceted lives to an essentialist category 'woman.' Rather gender, sex, and sexuality are not constrained by essentialist and narrowly defined categories, but are historically constituted, varied, and changing over time and space. The aims of feminist archaeology are to investigate and challenge the assumed content of, and relationships between, gendered categories such as women and men or femininity and masculinity. Feminist archaeology also seeks to study gender divisions and sexuality over time and in different social and cultural contexts in the past and in contemporary archaeology. Thus feminist/gender archaeology challenges traditional constructions of archaeological knowledge.

In the Beginning

Although tied to the goals of Second Wave feminism, which critiqued gender relations in contemporary society, feminism was slow in coming to archaeology. In the mid-1970s the first feminist critiques of equity issues in archaeology started in Scandinavia, particularly Norway. This concern quickly expanded to critiques of traditional analyses and presentations of women in the past and resulted in the founding of the first, and as yet only, feminist archaeology journal, 'KAN: kvinner i arkeologi i Norge' ('KAN: Women in Archaeology in Norway') in 1985. That same year Margaret Conkey and Janet Spector (1984) published their groundbreaking article critiquing androcentrism in archaeology and discussing the possibilities of studying gender in the past in the United States. It was not until the early 1990s, however, that the archaeology of gender and feminist critiques exploded on the archaeological scene. Since the first critical articles, there have been numerous publications on the archaeology of gender in journals, as well as monographs from symposia and conferences. Few of these publications use the word 'feminist' in their titles, preferring various combinations of the words 'gender' and 'archaeology.' However, the majority are often feminist in content and intention, and in their interpretations of the past.

Gender/feminist archaeology began largely as an Anglo-American, Australian, and Scandinavian phenomenon, but quickly expanded to other European countries and Latin America. The slow development of gender and feminist archaeology in some countries can be partially explained by how archaeology is understood within different academic systems. In North America archaeology and anthropology are closely linked, and archaeology benefited from its close connection with feminist anthropology. In European countries, however, archaeology is a humanity and thus society and social relations were traditionally not in the forefront of many studies. Archaeology is one of the few humanities that works with material culture and was relatively isolated from the intense feminist discussions in the humanities. This basic disciplinary difference between North American and European archaeology of gender is probably a reason for the different perspectives these two archaeologies initially had. North American gender archaeology has been concerned more with social processes while European gender archaeology continued with traditional interests in cultural (now gender) identity and distinctions. Feminist and gender theories were part of broader theoretical shifts in archaeology and anthropology that drew on social theories like poststructuralism and postprocessualism.

The feminist philosopher of science Alison Wylie (1991) asked why it took so long for feminist critiques to come to archaeology and emphasized the essentialist assumptions in archaeological theorizing inherent in macroscale analyses. Such essentialist assumptions were based on biological determinism and it was vital to make a distinction between sex, a biological construct, and gender, a social construct. Here one must note the difference between the English-language separation of sex and gender, and the fact that many other languages have but one word for both. Recent work in feminist archaeology, both in English and in non-English speaking countries, resurrects sex and sexuality from the merely biological, but while viewing sex/sexuality as a social construction associated with gender, this work does not neglect the relevance of biological processes for understanding identities.

Back to Basics

Much feminist work in the 1980s and 1990s concentrated on gender rather than sex and sexuality. This was, perhaps, necessary in order to negate the importance of previous biological determinism and essentialism. Androcentric archaeology considered women essentially the lesser part of the male–female, masculine–feminine, man–woman dichotomies. Women were often reduced to their biological function of giving birth. This also placed women on the lesser side of a whole series of related hierarchical dichotomies, such as public–domestic, public–private, dominant–dominated, active–passive, etc., thus giving biological reasons for social differences and social formations. This pattern was established in the archaeological literature before feminist critiques turned this set of universal hierarchical dichotomies into a problem to be investigated rather than assumed.

Conkey and Spector (1984) noted that despite its professed objectivity and neutrality, archaeology was 'neither objective nor inclusive on the subject of gender.' Traditional gender paradigms implicitly treated women and men differently, consistently linked certain activities to each gender/sex, and made men central and active in all societies in the past, while women were passive and 'at home.' Feminist interpretations of the same past critiqued the subordinate role given to women in archaeological analyses, texts, exhibits, and illustrations. Feminist archaeologists worked from the premise that universal subordination was not the case in the past, that gender ideologies and women's roles varied and were given different statuses over time and space, again emphasizing that these concepts are something to be investigated rather than assumed. Both feminist theoretical and empirical work assumed that gender categories were not exclusive and that women were an active part of culture and society in the past. Studies were concerned with defining women's various roles, contributions, and activities. The concept of task differentiation was developed by Janet Spector as a framework and methodology to study the various dimensions of women's and men's activities in society.

Following feminist critiques of science, feminist archaeologists critically examined the basic assumptions behind previous understandings of the past. Studies addressed archaeological understandings of what counts as data, what counts as interpretation of that data, and what is considered acceptable interpretation and theory in the archaeological community. Thus, they examined the selective processes through which scholars determined relevant data for interpretation and how these processes overdetermined interpretations and results by ignoring gendered processes and structures. Why are 'men's' artifacts simply assumed to be of primary interest? Why did important interpretational frameworks consider only men to be the prime movers of social and cultural change. In addition, they examined androcentric theoretical concepts that were previously, and often currently, considered to be the only reasonably legitimate, 'natural,' and 'rational' theoretical frameworks. Engendering the past not only redefines and extends what is considered as data, interpretation, and theory, but also challenges many taken-for-granted concepts and models.

Approaches to Gender and Sexuality

The archaeology of gender is grounded in the analysis and understanding of women's and men's lives as these are reflected in archaeological remains of the past and especially in the material culture of past societies. Richly detailed empirical studies, which put women, men, and children back in to our understanding of the past, abound. These studies are tied to differing theoretical views of gender as a structuring principle and how material culture is used to express and construct gender roles, differences, ideologies, and gendered identities in past societies. Foregrounding gender effects changes in traditional archaeological thinking and leads to an interest in social relations between genders and between gendered individuals of differing age, class, ethnicity, and race.

Engendered studies of Stone Age archaeology, for instance, have gone further than a concern with ecology and technology by considering the wider perspective of social relations between individuals and groups. Doing so leads to a restructuring of traditional archaeological interpretations, offering new insights into social relations, ideologies, and sociocultural institutions. Margaret Conkey (1991) considers the wider contexts in which tools were made, used, and reused at a Magdalenian site where several families lived ('aggregation sites'). By viewing tools not as single objects, but as objects representing a complex set of technological, productive, and engendered social relations, she is able to show the changing contexts of action and contexts for power in which people and objects were involved. Gender is always in process, the sexual/gender division of labor is often changed and negotiated, and these changing contexts of action are associated with the renegotiation of power relations and structures. Such analyses challenge traditional views of stable and exclusive gender categories and lead to analyses of archaeological material that can reveal different models of gender in society that may change in relation to particular contexts.

European archaeologists have made considerable use of burial material in discussions of the construction of gender. In her study of the Viking period Oseberg burial, a rich grave with the burial of two women in a ship, Elisabeth Arwill-Nordbladh (1998) uses Conkey's 'context of action' concept in relation to textile production, farm economy, communication, and ritual performance. Artifacts in the grave were analyzed in order to see how gender was constructed through various contexts of action. Gender construction is not seen as following a set of strict gender categories, but was maintained, changed, negotiated, or resisted through practice or performative acts. In this manner gender is seen as difference between and within gender categories, and the complexity of gender dynamics comes to the forefront. Working with grave material from the North European Bronze Age, Marie Louise Stig Sørensen (1991) presents a series of studies on how objects are active in expressing gendered identity. She especially examines how gender is constructed through appearance by examining the composition and placement of grave goods in relation to the body and in relation to their wider sociocultural contexts of use and meaning. In this manner it is possible to analyze not only gender but also crosscutting social categories such as age, ethnicity, and status.

Initially, the importance of gender in archaeology led to the neglect of the complexities of sex and sexuality. Concentrating

on gender lead to an initial neglect of sex and sexuality, but as feminist theory developed, so did interest in sexuality and the body as socially constructed and historically constituted, thus becoming important themes in feminist archaeology. Much of this work is on representations of the body in art, particularly in classical Mediterranean cultures and in studies of prehistoric rock art. Scandinavian rock art has a variety of human figures representing both female and, in particular, male figures. Inspired by feminist theory and Judith Butler's work on gender and the body, archaeologists critiqued traditional two-sex or no sex understandings of rock art figures using diverse analogies tied to variation in representations of bodies, ethnicity, mythologies, and rituals (Engelstad, 2001).

In the 1990s it became clear that gender archaeology was too concerned with 'finding women' and that the importance of men and masculinities, queer theories, and alternative interpretations and variation in gender entered the scene. Men and masculinity have been taken for granted categories that were assumed to be stable over time and space. Such male stereotypes as 'Man the Hunter' and 'Man the Warrior' are presented in the archaeological literature and are unchanging over diverse archaeological periods and cultures. A. Bernard Knapp was one of the first archaeologists to take up the neglected 'masculinist' approaches to archaeology, which he saw as 'derivative of feminist scholarship' (Knapp, 1998). He also saw Skogstrand (2010) ask the question "Is androcentric archaeology really about men?" since it actually recreates the same hunter/warrior stereotypes over time and space. She contends that this is a problem of objectivity and lack of critical reflection that has only recreated the same male stereotypes in archaeological analyses, and uses feminist critiques of androcentrism to decenter masculine stereotypes in historic and prehistoric archaeology. It is interesting that critique of these male stereotypes is now emerging in the context of feminist and gender archaeology.

There are various threads in feminist and gender archaeology, perhaps the most important of which is the distinction between the 'archaeology of gender' and the 'gendered archaeology' (Roberts, 1993), the latter of which has been discussed here as feminist archaeology. The archaeology of gender, while often premised on a feminist perspective and concerned with putting women and children back into our understanding of the past, reiterates traditional archaeological concepts and principles of interpretation. A gendered archaeology is explicitly feminist and closely tied to feminist critiques of science in an effort to generate new engendered ways of thinking, doing, and presenting archaeology. A gendered archaeology/feminist archaeology does not simply add women's contribution to past societies, but is concerned with interrogating and reworking our unquestioned starting premises and taken for granted concepts.

Practicing Archaeology

Although often considered to be neutral and objective, archaeological practice is highly gendered though often implicitly so. Feminist interests include archaeological practice, particularly fieldwork and analysis, workplace issues, pedagogy, cultural heritage management including museums, new ways of writing and presenting archaeology, and concern for the local communities in which archaeologists work.

Joan Gero (1996) looked at how fieldwork, particularly excavations and artifact analysis, is gendered. Gero has shown that observation and documentation are not neutral, objective processes but always contain an element of interpretation. Her work on excavations in Argentina shows that there are gender differences among who does different kinds of archaeological work and how documentation can be tied to differences in gender, class, and age. In North America and Europe men often lead large fieldwork projects, while women analyze extant collections. In Australia men dominate the universities while women dominate in work with cultural heritage management. In other countries gendered specialties and research foci take other forms; and although there were some prominent women archaeologists in the past, they had little access to status and recognition in the profession. Thus, the status of women and equity issues in the archaeological workplace continue to be major feminist concerns.

While an important aspect of feminist/gender archaeology is a concern with institutional structure and workplace dynamics that hinder women from fully participating in the discipline, feminist archaeologists are concerned with the communities within which they work. Another concern is with archaeology's and archaeologists' relationship to the indigenous communities within which they work. In Australia, Laurajane Smith has written about the dominance of women in work with cultural heritage, or cultural resource management related to indigenous communities. Feminists have been particularly open to the importance and meaning of local indigenous communities' heritage and its place in their past and future.

From Margin to Center

In a review article, Conkey and Gero (1997) noted the lack of explicit feminist theorizing and critique of basic archaeological concepts in much of gender archaeology. Detailed empirical analyses were perhaps necessary in the beginnings of gender archaeology. With the beginning of the second millennium it is clear that diverse theoretical perspectives are becoming common, although there is still a tendency for some implicit essentialism. A lack of theory only marginalizes the archaeology of gender, not only in relation to mainstream archaeology but also in relation to other feminist disciplines. Future work should strengthen efforts to include gender/feminism/sexuality in our construction of knowledge about the past.

Work grounded in feminist critiques, principles, and perspectives not only have made women visible but also shown the diversity of their lives and relations to others. Gendered and feminist archaeology has developed and changed considerably during its short existence. Feminist archaeology is exceptionally dynamic, drawing on new theoretical insights from other feminist disciplines, and expanding the scope and direction of analyses of gendered relations and ideologies in the past. Both gender archaeology and feminist archaeology will need to grapple with the fundamentals of, and variation in, archaeological material across time and space. Archaeological

interpretation and theorizing is now increasingly incorporating feminist theoretical insights on gender and sexuality.

Despite the seemingly initial small impact of many aspects of gender, feminist, masculinist, and queer archaeology (Danielsson, 2012; Danielsson and Thedéen, 2012), there are numerous important articles and books that are concerned with these themes in the archaeological literature. Gender/feminist archaeology is an important, complex, dynamic, and constantly expanding area of interest and is well on its way to realizing its critical and reconstructive potential.

Gender History

Kathleen Canning, University of Michigan, Ann Arbor, MI, USA

Abstract

Gender history emerged from women's history and represented a rejection of biological notions of sexual difference in favor of analysis of the cultural and social relations of the sexes. Its rise in Anglo-Saxon scholarship coincided with and was a vital part of the 'linguistic turn' during the late 1980s and early 1990s. Gender history has since widened its scope to encompass the study of men and masculinity. Gender history is also closely related to history of the body, while the history of sexuality/homosexuality is by now a distinct field of scholarly inquiry that is related to the history of gender but not dependent upon it.

Gender history examines the social and cultural, as opposed to natural or biological, relations of the sexes. The English term 'gender' is usually distinct from sex, which is understood as rooted in biological or bodily differences. The term gender does not exist in some languages, while in others its meaning diverges significantly from the English usage. The German term *Geschlecht*, for example, encompasses both 'sex' and 'gender' and thus blurs the core distinctions of the English term. In French the term 'sex' or *sexuel* is more commonly used than *genre*, which can refer to either grammatical or literary genre or serve as a classifying category in natural history (Riot-Sarcey, 1999). The historical category 'gender' emerged from feminist study of women's history during the mid 1980s. When the word 'gender' first gained currency among historians of women in the early 1980s, it was defined as signifying the social relations between the sexes. As the range and scope of scholarly research on gender expanded across the social, scientific, and humanistic disciplines, gender was increasingly understood as a symbolic system or signifier of relations of power in which men and women are positioned differently. By the end of the 1980s, the concept of gender came to encompass the languages, symbols, and social practices that defined sexual differences and sexual inequalities, signaling a more definitive departure of feminist social scientists from foundationalist notions of biological sex (Haraway, 1991).

The Analytic Origins of Gender History

By the turn to the 1990s, gender history – both in terms of its object of analysis and methodological approach – had distinguished itself from women's history, as well, although most practicioners continued to recognize women's history as a formative foundation for the study of gender in history. From the early 1960s on, feminist historians had set out to recover women's participation in and exclusion from processes of social transformations and political change. Empirical investigation of the private (familial, sexual) and public (political) inequality of women in past societies drove the first decade of women's history. The fact that women's history took shape during its formative years in interdisciplinary arenas, such as Women's Studies programs, explains why women's history became one of the most theoretically engaged fields of historical study during its early years, as feminists debated and critiqued the keywords of social analysis.

In this first phase of women's history, sex and class often figured as parallel forms of oppression: the female *sex* was viewed as a subordinate *class*, subjugated by a dominant *class* of men. In feminist scholarship the notion of *patriarchy* signaled a shifting understanding of sexual exploitation as the primary form of women's oppression (see, e.g., Rubin, 1975; Eisenstein, 1978). Taking patriarchy as a hierarchical sexual order, women's historians located its origins in 'the private family' and sought to examine the reproduction of patriarchy in social modes of production, divisions of labor, and property relations (Kelly, 1976). Analysis of the origins and practices of patriarchal structures and ideologies, along with the recovery of lost stories of female actors and women's agency, significantly expanded the scope of historical knowledge about women, family, and labor, while elevating 'sex' to a keyword of social analysis.

Yet in furnishing new insights into the place of women in past societies, the pioneering work in women's history soon revealed its own limitations. Unitary analytical categories, such as 'woman'/'women' and 'man'/'men,' based on fixed, rather than historically or socially variable, notions of biological sex, fostered narratives of women's experience or oppression that ignored differences of race, class, ethnicity, and sexual preference. Moreover, a fuller understanding of 'the significance of the *sexes*' in the historical past would require the study not only of 'the subjugated sex,' but of both women and men (Davis, 1976). At the end of the 1970s, feminist historian Joan Gadol called for a 'doubled vision' of society, one that emphasized the ways in which the identities of both men and women were shaped by sex and class (Kelly, 1979). In emphasizing the inextricable links between sex and class, women's history also indisputably widened the scope of the political to include family and household, bodies and sexualities – all once considered as belonging to the sphere of the 'private.' By the end of the 1970s 'sex' had emerged as a crucial category of feminist social analysis, one that was parsed in relation to race and class in scholarly debates.

Joan Kelly's formulation of this doubled vision of society marks a critical opening for the concept of gender, as feminist scholarship turned its attention to the ways in which ideologies, norms, and symbolic systems shaped sexual identities, relations, and sites of governance. The editors of the pioneering collection, *Sex and Class in Women's History* (Newton et al., 1983), for example, used the term 'gender' in order to understand the systematic ways in which 'sex differences' cut through

society and culture and conferred inequality upon women. Karin Hausen's path-breaking essay on the origins of 'sexual character,' situated the polarization of sexual stereotypes in Enlightenment philosophy, suggesting a temporal framework for the origins of modern gender distinctions (Hausen, 1981; Gleixner and Gray, 2006). Feminist historians delivered powerful critiques of the public/private dichotomy associated with the polarization of the sexes, widening the scope of the political to include family and household, bodies, and sexualities.

Even as gender began to forge its own analytical ground in the mid 1980s, it remained entangled for another decade or more in the analytics of women and sex. While feminist philosophers and theorists grappled with the sex/gender distinction (Nicholson, 1994), the terms 'women' and 'gender' remained loosely interchangeable in feminist history well into the 1990s and are still sometimes also described with the conjoined phrase 'history of women and gender' (Smith, 2000; Canning, 2006; Rose, 2010; Downs, 2010). The work of analytically distinguishing gender from women and from notions of biological sex was also propelled by transformations outside of academia. Through the broader public debates about 'identity politics' in the United States and Britain, once-cohesive ethnic, racial, national, or sexual identities were increasingly understood as multiple, mutable, and contradictory. Emphasizing the inextricability of gender and racial identities, feminist scholars of race issued powerful critiques of the unitary category of women and notions of patriarchal oppression (Higginbotham, 1992). Like gender, race also came to be viewed as a social construct rather than a genotypic or phenotypic form of difference.

Although the shift from women to gender was already well underway by the mid 1980s, the publication of Joan Scott's essay, Gender: A Useful Category of Historical Analysis (Scott, 1986), marked a definitive turn away from studies of patriarchy and of women's economic, sexual, or reproductive subordination grounded in notions of physical differences between the sexes. Scott summoned 'mainstream' historians to consider gender as a constitutive element of social relationships based on the 'perceived differences' between the sexes, as expressed in culturally available symbols, normative concepts, notions of politics and institutions, and subjective identities. Moreover, Scott argued, gender had become an essential category of historical analysis because it is a primary way of signifying relationships of power. Gender thus gained an analytic status of its own, first by severing the links between sex-gender and biology, and then by freeing it from the remnants of Marxism that hinged the production of gender to changing economic structures. Scott's article, followed by her essay collection, *Gender and the Politics of History* (Scott, 1988), unleashed a torrent of debate over the implications of gender for methodological approaches to historical causality and processes of change. Scott called upon historians to shift their attention from 'objective processes,' such as industrialization and urbanization, to the discursive, linguistic, or symbolic representations of sexual difference that, for example, institutionalized the sexual division of labor in late nineteenth century France or that produced women workers as 'objects of (state) investigation and subjects of history' (Scott, 1988, 1993).

Understood as a cultural, linguistic, or discursive construct, gender had a central place in the broader paradigm shift known as 'the linguistic turn' in the discipline of history. The controversies accompanying the rise of gender history thus involved the objects of historical investigation – women of the past versus historical discourses, languages, or symbols – and the methods of historical analysis, which in the wake of the linguistic turn came to include Foucauldian social theory, new historicism, as well as poststructuralist linguistic and literary theory (Poovey, 1988b; Canning, 1994; Surkis, 2012). At the same time feminist philosopher Denise Riley interrogated the category 'woman' in her *Am I That Name?* (1988), noting the inherent and historically grounded instability of the category termed 'woman' and identifying feminism as the precise site at which that instability was systematically contested, taken apart and reconstructed. These dual impulses – the critique and disassembly of the category of 'woman' and the advancement of a new analytic concept of 'gender' – effectively redefined and resituated the keywords of feminist history: woman, sex, and feminism. Soon other keywords of social history, such as 'experience,' 'identity,' and 'agency,' were also subject to critical debate and redefinition.

Yet the rise of gender as a category of historical analysis did not have the effect of asserting the primacy of gender relative to other forms of inequality, such as race, class, or ethnicity. Rather, the emphasis on the inextricable links between gender and other social identities and categories of difference sparked critical engagements with categories of race and class as well. In the United States and Britain, feminist scholars of race intervened at this juncture with powerful critiques of the categories and practices of women's history. Defining race as a 'metalanguage,' and the 'ultimate trope of difference,' African–American historians explicated the powerful effects of race on the construction and representation of gender, class, and sexuality. Understanding race as a 'double-voiced discourse' revealed the ways in which it shaped both the oppression and self-representation of minorities (Higginbotham, 1992).

Rewriting History after the Turn to Gender

The turn to gender, like all theoretical and methodological innovations, was an uneven and protracted process that has differed markedly across different temporal and geographical fields. In some fields scholars sought to redefine methodologies, concepts, and theories to meet the challenge posed by the concept of gender, while in other fields women's history was quietly renamed 'gender history' without a recognizable shift in historical methodology. In national historiographies, in which the work of recovering absent female subjects had a later start, historical research on women has continued to provide the foundation for a more explicitly theoretical engagement with gender well after the turn to the twenty-first century. In still other settings, where the turn to gender history coincided with the rediscovery of masculinity and men, gender history came to denote a more thoroughly relational engagement with the histories of both masculinity and femininity.

While women's history once sought to fit female subjects into existing categories of social analysis, such as class, nation, and citizenship, the turn to gender prompted more fundamental critiques and redefinitions of these keywords of social analysis. The concept of 'class,' for example, was at the heart of debates about both gender and the linguistic turn, leading some feminist scholars to call for an emancipation from class as a 'privileged signifier of social relations and their political representations' (Alexander, 1984), while others analyzed the formation of both the middle-class (Davidoff and Hall, 1987) and the working-class (Clark, 1995) as processes of differentiation in which gender was always centrally implicated. Eschewing models of class formation that sought to delineate economic, social, cultural, and political levels or stages of development, feminist historians of gender examined class as a political language, emphasizing the significance of gender in the process of assigning and contesting the boundaries and meanings of class (Scott, 1988; Sewell, 1990; Canning, 1992). The 'public/private divide' and its specific historical and gendered meanings for class, citizenship, public sphere, and nation-state formation was the topic of two issues of the *Journal of Women's History* (2003/1 and 2003/2) that offered theoretical perspectives and historical comparisons with case studies of Britain, Brazil, the United States and the Middle East. Other social-scientific keywords, like 'public sphere' (Fraser, 1992; Ryan, 1992), 'civil society' (Pateman, 1988; Hull, 1996), and 'citizenship' (Lister, 1997; Canning and Rose, 2002) have also been sites of fruitful rethinking by scholars of gender. Similar to the location of class in socioeconomic structures, citizenship is embedded in legal and constitutional frameworks and theories of state and nation formation. Feminist social scientists critiqued teleological models of citizenship, like T.H. Marshall's classic, *Citizenship and Social Class* (1950) that outlined the progressive acquisition of civil, political and social rights, pointing instead to the nonlinear trajectories by which women acquired rights, often first as social citizens and only much later, as political citizens. Feminist scholarship has probed the meanings and practices of citizenship beyond the law, exploring the rhetorics, claims, and subjectivities of citizenship, which are also taken up by those lacking and thus demanding citizenship rights.

Breaking up the binary oppositions of public and private/political and personal, also led to fruitful new research on the history of consumption from a gendered perspective. Although consumption has historically been identified with femininity, Davidoff and Hall's *Family Fortunes* (1987) argued convincingly that domesticity, the ideology of the British middle classes, was vested in complex and elaborate practices of consumption and display. With gender as a framing concept, the historical study of consumption has expanded in recent years to encompass analysis of commodification, spectatorship, material culture, popular culture, leisure, and fashion, which are vital dimensions of gendered social identities, not least as an arena in which these gendered identities were performed, critiqued, recast, and subverted (DeGrazia and Furlough, 1996; Peiss, 1998). Studies of consumption also explore its place in shaping gendered boundaries of class, citizenship, and cultural belonging (Cohen, 2003) and have also spurred new explorations of visual culture, fashion and beauty, marketing and advertising, both in transnational dimensions (Modern Girl, 2008) and as a vital aspect of the relationships between empires and metropoles (McClintock, 1995).

Masculinities

If the redefinition of keywords of social analysis was one outcome of gender history, its explicit attention to the relations between the sexes prompted the opening of gender history toward a more serious study of men and masculinity. The embrace of gender had been controversial in part because women's historians had feared that emphasis on the mutual constitution of masculinity and femininity would obscure both male oppression of women and female agency (Bock, 1991). The advent of men's studies in the early 1990s – marked, for example, by the founding of the American Men's Studies Association in 1991 and its journal *The Journal of Men's Studies* in 1992 – led feminists to observe that men, unlike women, had hardly been 'hidden from history.' While feminists worried that inquiry into the ideals of manliness and their imposition on men of the past might conceal the ways men had participated in and benefited from the oppression of women (Brod, 1994), historian John Tosh concluded in 1994 that the 'gendered study of men' and masculinities had become 'indispensable to any serious feminist historical project' (Tosh, 1994). As the category of 'masculinity' soon overtook that of 'men,' theoretical approaches to masculinity were refined in the disciplines of sociology and philosophy by Harry Brod (1994), R.W. Connell (1995), and Michael Kimmel (1996). A founding text in the field of history was George Mosse's *The Image of Man: The Creation of Modern Masculinity* (1996), a comparative study of ideal types of masculinity in European and American history since the early nineteenth century. Subsequent histories of masculinity examined ideal or hegemonic masculinities, masculinities as shaped by class (Hall, 1992; Clark, 1995; Frevert, 1995), citizenship (Dudink et al., 2007), race (Bederman, 1995), colonialism (Sinha, 1995), militarism (Kühne, 1996), and homosexuality (Chauncey, 1994; Puff, 1998; Rocke, 1998; McLaren, 1999b). One achievement of the history of masculinity has been to 'demonstrate that gender is inherent in all aspects of social life, whether women are present or not' (Tosh, 1994). While masculinity is generally regarded as an inherently relational category, femininity has scarcely had a parallel significance in the study of gender. Historian Stefan Dudink contends that the focus on masculinity reflects the 'asymmetry of gender relations' by which masculinity has remained unmarked amidst the universal categories of 'men,' 'mankind,' and 'humanity' (Dudink, 1998), while femininity, which was 'never allowed to pass as the universal,' was more visible and thus less in need of a similar kind of unmasking.

Entwined Terms: Genders/Bodies/Sexualities

Body/Bodies

Other key terms in the vocabulary of interdisciplinary gender studies, which were redefined in the course of the paradigm shift

from women to gender are 'body' and 'sexuality.' During the first wave of women's history, the body served as the foundation for the shared experiences and identities of women. As a term deeply embedded in biologism and essentialism, body was inextricably linked to sex before the 'linguistic turn' began to disentangle these terms. The 'discursivation' of the body, which took place in the course of the 'linguistic turn,' detached it from unchanging notions of physical difference, but it also appeared to sweep away any sense of bodily physicality or materiality. No longer the foundation of experience, nor the somatic location of identity, the ambiguous status of the body between discourse and experience prompted a wave of debate through the end of the 1990s (Haraway, 1991; Butler, 1993; Bynum, 1995; Canning, 1999). As these debates raged, the body moved to the center of methodological debates in feminist theory, which established conceptual frameworks for the 'full range of bodies' that had emerged from two decades of scholarship – body image; body performance; bodies in science, medicine, and technology; bodies in space; virtual bodies; lived or situated bodies; the body politic; and embodied ideals/ideologies (Bordo and Jaggar, 1989; Martin, 2001; Schiebinger, 2000).

At the same time 'body history' came to designate a pluralistic field of scholarly inquiry of bodies as significant dimensions of specific social, cultural, and political processes, such as the laboring body, the regulated/disciplined body; the medicalized or scientized body; the idealized body of nation, state, or king; the embodiment of theology and the place of the body in cultural or religious rituals; or body and memory in situated life histories (e.g., Outram, 1989; Roper, 1994). An important outcome of historians' engagement with the legacy of Michel Foucault for the study of bodies as sites of regulation and governmentality is the broad recognition of 'biopolitics' as a crucial form of modern governance. While Rublack (2012) suggests that early modern persons' sense of self – or subjectivity – was experienced as 'deeply embodied' and was both interlinked with the physical and emotional yet also 'interrelated with the external world,' the modern body is defined by the ways it is viewed, measured, mobilized, disciplined, and governed by the ideologies and technologies of states, social reformers, medical experts, nationalists, and industrial paternalists. Moreover, the modern body had individual and collective or social dimensions, reorganizing social and material life around hygienic principles while instilling in individuals the skills of self-care and self-discipline. The collectivized body or social body was cut through with social distinctions of class, ethnicity, and gender (Poovey, 1995).

If research on the hygienic and social body relied upon well-documented practices of states, as well as medical and social reform institutions, the gendered body as site of experience or agency was much more difficult to trace historically. Hence few historical monographs could be considered histories of the body in this sense, with the important exception of Barbara Duden's enduring classic *Woman in the Body: A Doctor's Patients in Eighteenth Century Germany* (1991), which analyzes the testimony patients left behind about their own bodily perceptions, sensations, and agency in an era when women still possessed 'interpretive authority' over their bodies. The transfer of this interpretive authority to male experts is one of the markers of the modern body. More recent studies of empire, colonialism, and global and transatlantic traffic in people and goods have placed bodies at the heart of the colonial encounter (Burton and Ballantyne, 2005; Brown, 2011) and analyzed bodily sensations, sensory experiences, and memories as part of the 'emotional economy of the everyday' in colonialism (Stoler and Strassler, 2000; Stoler, 2002; Hunt, 2008).

While 'body history' as a distinguishable field of historical inquiry has diminished in the last decade, two of its keywords remain salient for current historical inquiry – corporeality and embodiment. Corporeality can be understood as encompassing the social, cultural, and/or political significance of bodily being; encompassing bodily images/symbols, regimes, and strategies of bodily governance; and bodily perceptions, interpretations, and self-representations that are specific to a given temporal and spatial context (Mazzio, 1997). Why and how the corporeal dimensions of state policies or social movements, of class or ethnic conflict become visible, varies according to the specific historical setting. The notion of embodiment refers to the ways subjects and the social collectivity assign meaning to bodies, interpret and act upon them (Grosz, 1994; Gatens, 1996). No longer embedded in a dichotomy between discourse and agency/experience, embodiment does not presume resistance or subversion, encompassing instead the capacity of humans to assign meaning to and act upon their own bodies, often in unexpected ways.

Sexuality

Gender and body remain crucial analytics in the history of sexuality, an expanding and highly productive arena that has recently repositioned both gender and body as concepts and fields of scholarly inquiry. The focus of early histories of sexuality melded sexuality with gender, reproduction, and body, examining topics such as prostitution, contraception, abortion, sexual reform, adultery, masturbation, and venereal disease (e.g., Walkowitz, 1982, 1992; White, 1990; Grossmann, 1995). Studies of lesbianism and male homosexuality had the productive effect of destabilizing gender categories by breaking up the binary oppositions of male/female, masculine/feminine, and by unmasking 'the epistemic regime of presumptive heterosexuality' (D'Emilio, 1983/1998; Chauncey, 1994; Puff, 1998; Butler, 1990; Fausto-Sterling, 2000). With the founding of the *Journal of History of Sexuality* in 1990, the history of sexuality marked out its own terrain, distinct from the history of gender, coinciding with a decisive turn toward studying sexual politics as situated within and vital to broader historical processes of transformation, such as the formation of civil society, the inception of citizenship, or the pursuit of empire (Hall, 1992; Engelstein, 1992; Stoler, 2002; Surkis, 2006). Influenced by the work of Michel Foucault, the history of sexuality also focused on the specific domains within nation-states where sexualities were produced, such as systems of medical knowledge and state regulation that distinguished normal from 'deviant' or 'marginal' sexualities and that dispersed these definitions throughout the institutions of state and social reform (Mort, 1987; Nye, 1999; Eder et al., 1999).

In the last several years, as the influence of the Foucauldian paradigm has loosened, scholars have posed new questions about the periodicity, i.e., the implicit modernity of homosexuality and of sexuality more generally (Puff, 2012; Wiesner-Hanks, 2012). With histories of male and female sexuality as one of the 'prime movers' in the history of sexuality (Puff, 2012), its practitioners have examined the meanings of sex acts (Puff, 2003) and the emergence of homosexual subcultures and movements for emancipation (Chauncey, 1994; Lybeck, 2012). The history of sexuality has also been influenced by the transnational or global turn, exploring more recently the ways in which sexual cultures and identities transcend national boundaries and are shaped by the transnational flows of individuals, ideas, and movements (Aldrich, 2006; Rupp, 2009; Canaday, 2009; Herzog, 2011). Recent literature also reveals a marked shift away from their longstanding focus on such matters as population politics, hygiene, sexual science, and the normative construction of sexual identities toward examination of the formation of the sexual subject or a modern sexual self (Eder, 1999; Oosterhuis, 2000). Matysik (2012) proposes a view of sexuality that is situated in body and mind, while other scholars call for closer examination of intimacy, emotions, and memory in the construction and experiences of sexuality within life-worlds (Dickinson and Wetzell, 2005; Spector et al., 2012). While sexual histories of war, Nazism, and post-war reconstructions remained unexplored or were still highly controversial a decade ago, these topics have formed some of the most fruitful inquiries in the field during the past several years (Heineman, 2002; Herzog, 2004, 2007, 2011; Evans, 2011).

Outlook for the Future

After nearly three decades of scholarship, the history of gender is a well-established field, as evidenced by the number of chairs and teaching positions assigned to this scholarly field and the continued vitality of the field as represented in scholarly journals and academic book publishing. The debates of the past about the prospects of gender history entering the 'mainstream,' i.e., moving from the status of the margins to the center of historical scholarship have dissipated, not because gender history has achieved parity or equal representation therein, but because the very notions of mainstream and margins have themselves changed considerably during the last two decades. Rather, gender history has become a much more pluralistic undertaking, both in terms of historical methodologies and the scope of topics encompassed under the rubric of 'gender.' Gender history is most often a cultural historical inquiry, one that probes the rhetorics, languages, symbols, and discourses that shape femininity and masculinity as ideologies, practices, and performances. Yet historians have renewed interest in recent years in the social dimensions of gender, in the gendered relations and experiences of empire, colonialism, slavery, labor, poverty, immigration, and other dimensions of 'the social.' While the study of masculinity is a well-established inquiry within gender history by now, women – as subjects and objects of historical investigation – remain a vital presence in many studies of gender. In fact, 'gender and women' are still frequently paired in the titles of books, courses, or conference panels today. If gender history had a part in spawning the study of the body and of sexuality, today the history of sexualities is an established field that is in no sense beholden to gender history, not least because queer studies and the history of homosexuality have constituted its driving force during the last two decades (Puff, 2012). The analytic of 'gender' has thus been enriched and enlivened internally, as historical practices attended to the study of both femininity and masculinity and the relationships between them. Gender history has also been repositioned by the terms that surround it – body and sexuality – and by historical study that considers the connections and distinctions between and among them in specific historical settings.

Abstract

This article explores gendered patterns of time use as an explanatory factor behind fertility trends in the developed world. We review the theoretical foundations for this link, and assess the existing evidence suggesting that a more equal division of labor within the home leads to more children, both at the household (micro) and country (macro) levels. After decades of unprecedented fertility decline in the industrialized world, only a handful of countries in the West exhibit replacement fertility rates, around two children per woman. Paradoxically, birth rates are substantially lower in countries in which family units (and women within families) remain primarily responsible for familial care obligations, and where the role of the state in the provision of care services is marginal. Very low-fertility poses challenges for economic growth and threatens the sustainability of pay-as-you-go welfare systems. It is thus important to understand why some developed countries managed to sustain near-replacement fertility rates or to recover from very low fertility, while others fell and still remain at lowest-low rates of about 1.3 children per woman. Looking at time-use and fertility trends for a few representative industrialized countries, we hint at the existence of a threshold ratio of gender equity in the distribution of domestic work that low-fertility countries need to cross before being able to enter a phase of fertility recovery.

Introduction

During the 1980s, total fertility rates (TFR) in most advanced societies fell below 2.1 children per woman (Van De Kaa, 1987), a level known as *replacement fertility* – two children to replace their parents, and the remaining fraction to compensate for those who will remain childless or die before the end of their reproductive lives. Within the next decade, an important proportion of Southern and Eastern European countries – e.g., Russia – reached rates below 1.3 children per woman (Billari and Kohler, 2004; Kohler et al., 2002), a level known as *lowest-low fertility*. Very low-fertility poses challenges for academics and policy makers alike, as shrinking and aging populations jeopardize economic growth and threaten the sustainability of pay-as-you-go welfare systems. In the absence of offsetting changes in employment rates and productivity, structural adaptations may be required, with important implications for public pensions, health expenditures, and welfare (Weil, 1997).

Recently, scholars have documented a process of fertility recovery in several countries, particularly in the US and in Northern Europe (Goldstein et al., 2009; Sánchez-Barricarte and Fernández-Carro, 2007). This uptick in fertility might currently be spreading to other countries (Myrskylä et al., 2013; Sobotka, 2011) and possibly to more advanced regions within lowest-low fertility countries such as Italy (Caltabiano et al., 2009). Even if these trends might partially be attributed to methodological differences in the measurement of fertility (Bongaarts and Sobotka, 2012), the fact remains that recent fertility declines were not homogeneous across the West, stabilizing near replacement in some countries and falling to substantially lower levels in others. Paradoxically, fertility sank deepest in countries with a strong *familialistic* social policy (e.g., Southern Europe), where the role of the State in the provision of care services is marginal, and family units – and women within families – remain primarily responsible for familial care obligations (Esping-Andersen, 2009).

This article contributes to the existing fertility research by taking a multidisciplinary approach from demography, sociology, and economics to identify an emerging area of research at the intersection between fertility and the gendered distribution of household labor. We use time diary data to present new cross-country evidence on the association between time use, gender, and fertility. This approach can provide new insights as we seek to understand lowest-low fertility and the forces behind fertility recovery.

The article is organized as follows. We begin by documenting the unprecedented fertility decline observed in industrialized countries after 1970, and highlight some of the sociological and economic explanations that have been advanced to explain these trends. Next, we review the theoretical link between fertility and gendered patterns of time use, and assess the existing evidence indicating that a more equal gender division of labor within the home leads to more children. We further investigate this hypothesis by comparing, for a sample of representative industrialized countries, trends in fertility and in the gender distribution of domestic work during the past 50 years. We close with the identification of avenues for future research.

Fertility Decline, Ideational Change, and Opportunity Cost

The theory of the second demographic transition (SDT) (Lesthaeghe and Surkyn, 1988; Lesthaeghe, 1995, 1983) attributes recent fertility declines to a process of ideational social change, by which fertility is no longer driven by concerns regarding basic human needs (food production in the home economy, old-age support and insurance, child survival, etc.), but geared instead toward the satisfaction of higher-order, post-materialistic needs (self-realization, expressive values, etc.) which do not require high fertility to be met. The SDT predicts structural below-replacement

fertility in advanced populations (Lesthaeghe, 2007). Some authors even suggested that most countries would be trapped into very low-fertility rates due to a combination of demographic (fewer women being born resulting in fewer future births) and sociological (declining fertility preferences derived from increased exposure to very low fertility) factors, among others (Testa et al., 2006).

The economic perspective relates fertility decline with increases in the cost of children, in particular the opportunity cost of time. Becker's original model of time allocation suggested that, as time became more valuable, the production and consumption of time-intensive 'commodities,' such as children, would be lower (Becker, 1965). Thus, increasing labor market opportunities for women would lead to higher female labor force participation and to fewer children (Becker, 1965; Willis, 1973). The increase in female wages over the past few decades is assumed to be unrelated to fertility declines; instead, female wage gains are attributed to factors such as technological change, which decreased the reliance on physical-intensive labor in favor of cognitive-intensive work, a transition which, arguably, suited better the labor market abilities of women (Galor and Weil, 1996). In addition, the diffusion of oral contraception contributed to marriage postponement and facilitated greater career investments from women (Goldin and Katz, 2002). Complementarily, the diffusion of home appliances played an important role in easing the demands of housework, increasing the responsiveness of female labor supply to changes in wages (Greenwood et al., 2005). Becker's prediction of a negative relationship between (female) wages and fertility was initially confirmed at the macro (Mincer, 1985) and micro levels (see Schultz, 2001, for a review of this literature). As we will see in the following sections, this relationship would be challenged later using more recent data.

The Heterogeneous Fertility Decline in Advanced Economies

Fertility declines were not homogeneous across countries, resulting in varying birth rates among industrialized nations. As a result, today some countries exhibit TFRs near two children per woman, having managed never to drop far from replacement rates or to recover fertility. In contrast, fertility in some other countries remains substantially below replacement. This is illustrated in **Figure 1**, which presents fertility trends in select OECD economies from 1970 to 2011. We distinguish between two groups of countries: those where fertility did not decline as much or recovered (United States, Denmark, Finland, and Norway) and those in which fertility decreased substantially over this period and remained at very low levels. The latter – Italy, Spain, Germany, and Japan – present TFRs approximately 1.3 children per woman since the early 1990s, a level known as lowest-low fertility.

The experience of fertility recovery in some countries challenged SDT's predictions of long-term low fertility and the hypothesis of a low-fertility trap, by showing that countries can approach near-replacement fertility from below, that is, after falling to lower levels. Indeed, SDT theory has been recently updated to account for rebounding fertility rates (Lesthaeghe, 2010). Similarly weakened is Becker's prediction of an inverse relationship between female wages and fertility, which no longer holds at the macro level. In the past, countries with lower female labor force participation rates had higher-fertility levels, and vice versa (Mincer, 1985), suggesting role incompatibility between the roles of mother and worker (Stycos and Weller, 1967). However, this relationship reversed in some nations after the mid-1980s (Brewster and Rindfuss, 2000; Murphy, 2001) and, today, fertility is lowest in countries with lower female labor force participation rates (Ahn and Mira, 2002; De Laat and Sevilla-Sanz, 2011).

Figure 1 Total fertility rates in selected industrialized countries. Note: Total fertility rate (TFR) indicates the number of children that an average woman would have at the end of her reproductive life were she to follow the age-specific fertility patterns observed in a given population at a given time. Source: OECD, 2012. OECD Family Database, OECD, Paris. www.oecd.org/social/family/database.

Gendered Patterns of Time Use and Fertility Recovery

Two main developments are behind the fertility trends described above. First, male and female employment rates have been converging in OECD countries since the 1970s (Jaumotte, 2003). Second, men are increasingly involved in housework and childcare, especially in high-fertility countries (Aguiar and Hurst, 2007; Bianchi, 2000; Gimenez-Nadal and Sevilla, 2012; Kan et al., 2011). From these observations, a theory has emerged in parallel within sociology, demography, and economics, focusing on gender equity in the distribution of family responsibilities. This theory predicts that couples in which the man and the woman share equitably in home and market production will exhibit higher-fertility outcomes than couples with a more gendered time use pattern. Gender equity in domestic work allows women to combine the rearing of children with market work, a preference shared by most women in advanced economies (Hakim, 2000). Higher-fertility levels can thus be compatible with greater female labor force participation, as long as men take up a fair share of household responsibilities: see De Laat and Sevilla-Sanz (2011) for formalization and application of this theory, and Bettio and Villa (1998) for a similar argument.

This theory could also help explain the process of fertility recovery observed in some countries, and the lack of recovery observed in others. Fertility recovery would thus depend on changes in the household division of labor, driven by gender norms. In particular, when women's wages are low, as they were before 1970 in most developed countries, women specialize in childcare and housework, having children comes with a low opportunity cost, and couples have more of them. In this context, social norms and economic considerations align as observed in the neoclassical home economics approach (Becker, 1991). Esping-Andersen (2009) calls this the traditional 'male breadwinner, female homemaker' equilibrium. However, as women's wages rise, as they did after 1970, women's bargaining power increases and efficiency considerations (i.e., staying at home becoming relatively more costly) lead to less household gender specialization. A 'gender egalitarian' equilibrium is eventually reached, characterized by greater gender equity in the distribution of family duties, high female labor force participation, and fertility rates near replacement (De Laat and Sevilla-Sanz, 2006; Esping-Andersen et al., 2013; Feyrer et al., 2008; Goldscheider, 2012). However, there is an intermediate phase in which women's new labor market opportunities conflict with slowly evolving social norms, expectations that women are chiefly responsible for home production. In this middle stage, the high opportunity cost of time derived from increased female wages places additional stress on women, who face a 'double burden' of market work and childcare (Hochschild and Machung, 1989; Milkie et al., 2009).

Using this theoretical approach, current cross-country differences in fertility rates could be explained, *ceteris paribus*, by the different gendered time-use patterns. Why have some countries completed the transition to a more gender equitable use of time faster than others? Borrowing from McDonald (2000a,b), some authors argue that family policy is the main force behind these trends, since it promotes gender equity in settings, such as the tax code and paternity leave policy, that deal with people as members of families (Esping-Andersen, 2009). Other scholars stress the importance of social norms, particularly those dealing with men's role in the family, and argue that the gender revolution will complete only when norms are more gender neutral (Goldscheider et al., 2013). In any case, both approaches hinge on the growing body of evidence indicating that when men and women share more equitably in the worlds of work and home, couples reach higher levels of fertility (Esping-Andersen, 2009; Goldscheider, 2012).

As with aggregate fertility rates, similar patterns are observed at the household level: greater intra-household gender equity is associated with faster transitions to parenthood and to higher-order births, and with higher completed fertility. This general pattern is confirmed in a variety of countries, using several estimation techniques (Brodmann et al., 2007; Cooke, 2009, 2004; Goldscheider et al., 2013; Oláh, 2003). There is evidence for a U-shaped curve at the household level: couples with a traditional distribution of household responsibilities (male breadwinner, female homemaker), as well as those with more equitable gender roles, are more likely to transition to a second birth than couples with unequal but not specialized division of labor (Torr and Short, 2004).

Evidence from Time Diary Data

Studies of fertility and the distribution of household responsibilities usually approximate time use patterns using gender attitudes and other proxies (such as father's use of parental leave). In contrast, time diary data provide a more accurate and direct picture of the gender division of domestic labor. A diary is completed by respondents on selected days, which are divided into intervals. For each of these intervals, respondents report the main activity they are engaged in, among other things (such as whether they were performing that activity alone or with others). In the remainder of this article, we use time diary data from the past five decades to explore fertility trends in eight industrialized countries, and present some plausible hypotheses that could inform further research.

Table 1 shows average fertility rates and gender patterns of time use for the eight countries in **Figure 1**, for the early 2000s. Gendered patterns of time use are defined as the men-to-women ratio of time spent in a given activity. We distinguish between housework, childcare, and paid work. Countries are ranked by fertility rates, with those at the top (USA, Norway, Finland, and Denmark) exhibiting a more gender egalitarian distribution of time. Men in these four near-replacement fertility countries devote over 50% of woman's time to housework and only between 50% and 85% more time than women to paid work. In contrast, in lowest-low fertility countries (Germany, Japan, Italy, and Spain) men's share in housework time is less than half of women's, with over twice as much time devoted to paid employment. There are only slight differences across groups in time devoted to childcare (these are uncommonly large

Table 1 Fertility and gender patterns of time use, 2000–04

		Ratio of men/women time devoted to:		
	TFR	*Childcare*	*Housework*	*Paid work*
Near-replacement fertility				
USA	2.04	0.52	0.54	1.84
Norway	1.80	0.45	0.67	1.81
Denmark	1.76	0.51	0.73	1.54
Finland	1.75	0.42	0.59	1.52
Lowest-low fertility				
Germany	1.35	0.43	0.48	2.48
Japan	1.32	0.17	0.06	2.11
Italy	1.28	0.41	0.22	2.67
Spain	1.27	0.42	0.27	2.62

Note: Multinational Time Use Study (MTUS) is an ex-post harmonized cross-time, cross-national comparative time use database, constructed from national random-sampled time-diary studies. The sample is restricted to individuals aged 20–59 years, living with a partner in a household with at least one child under the age of 18 years.
Sources: OECD, 2012. OECD Family Database, OECD, Paris. www.oecd.org/social/family/database and MTUS, Jonathan Gershuny and Kimberly Fisher, with Evrim Altintas, Alyssa Borkosky, Anita Bortnik, Donna Dosman, Cara Fedick, Tyler Frederick, Anne H. Gauthier, Sally Jones, Jiweon Jun, Aaron Lai, Qianhan Lin, Tingting Lu, Fiona Lui, Leslie MacRae, Berenice Monna, José Ignacio Giménez Nadal, Monica Pauls, Cori Pawlak, Andrew Shipley, Cecilia Tinonin, Nuno Torres, Charlemaigne Victorino, and Oiching Yeung, 2012. Multinational Time Use Study, Versions World 5.5.3, 5.80, and 6.0 (released October 2012). Centre for Time Use Research, University of Oxford, United Kingdom. www.timeuse.org/mtus/. Because of lack of more recent harmonized time diary data, we report averages for the period 2000–04 period for all outcomes. Time use data for Japan come from the Survey on Time Use and Leisure Activities (2001).

in Japan) with women doing on average about twice as much as men; still, men's contribution to childcare is marginally higher in near-replacement countries.

Two other interesting facts emerge from these data. Firstly, there are greater cross-country gender differences in housework and paid work time than in childcare time, suggesting that parents treat childcare, but not housework, as a form of investment (Guryan et al., 2008); as such, childcare may be less subject to change as a result of evolving social norms. Secondly, perfect gender equality (a value near 1) does not seem to be a requisite for near-replacement fertility levels; in fact, even the more egalitarian societies are far from full equality in these three important daily activities: childcare, housework, and paid work.

To further explore the fertility recovery hypothesis, **Figure 2** presents the time series of fertility, female labor force participation, and domestic work (measured here as the sum of housework and childcare time) for selected countries within each fertility group. In countries with current fertility levels near replacement (USA and Norway), fertility declined until the 1980s, but then a threshold ratio of men-to-women domestic work time (about 0.5) was crossed, and they began to recover fertility. In contrast, countries with lowest-low fertility levels (Italy and Spain) have yet to cross such threshold, and show no sign of sustained fertility recovery. Even more, these countries seem to be at different stages of a similar process: the gender pattern of domestic work observed in low-fertility countries at the beginning of the 2000s is remarkably similar to that of near-replacement-fertility countries in the 1960 to 1970s. However, new research (Sullivan et al., 2014) shows that, among lowest-low fertility countries, early signs of fertility recovery are associated with greater participation in domestic work among educated young men; to the extent that gender equitable attitudes diffuse, this could lead to future fertility gains among lowest-low fertility countries.

Conclusion and Further Research

In the industrialized world, fertility declines varied in rates and timing across countries, resulting in two broadly defined fertility regimes. In some countries, such as the USA and Northern Europe, fertility never fell far below the replacement rate of 2.1 children per women, or bounced back and stabilized near that level. In Southern Europe, Germany, and Japan, fertility declined to substantially lower levels without recovery. In this article, we reviewed an expanding area of research located at the intersection between fertility and the gender distribution of household labor, and presented cross-country evidence from time diary data suggesting that increases in men's share of home production might partially explain fertility recovery in advanced economies.

Some questions remain which deserve further consideration. More could be said on the role of attitudes in mediating the relationship between gendered time use patterns and fertility. Goldscheider et al. (2013) report that, in Sweden, what most depresses couples' fertility is the inconsistency between gender attitudes and behaviors: when 'reality' in the distribution of housework (but not childcare) disagrees with women's 'ideals' of fairness, second births (but not other-parity births) are significantly delayed. Similarly, Brodmann et al. (2007) find that the effect on fertility of a higher male contribution in housework is stronger for career-oriented women.

This area of inquiry could also benefit from interdisciplinary dialogue. Complementary to arguments about gender equity and fairness – prevalent in sociology and demography – policy intervention could attend to reasons of economic efficiency. Prior economic research has identified peer effects and positive externalities in the spread of social norms and the diffusion of gender-equitable behaviors (De Laat and Sevilla-Sanz, 2011), which in turn may affect childbearing decisions (Fernández and Fogli, 2006). Under positive externalities, couples who do not engage in egalitarian behavior can still free-ride on the benefits from higher aggregate fertility resulting from couples engaging in more equal division of labor. As a result, the number of egalitarian couples would be less than socially optimal. This suggests that, even if targeted to a limited number of individuals, intervention to reach a more equal sharing of housework and to increase fertility, would have rippling effects by increasing the fertility of other couples. Similarly, inefficiencies in the distribution of household chores and in the achievement of desired fertility could arise from imperfect information among partners. Given the 'public good' nature of children in the family (Lundberg and Pollak, 1993), and the difficulty in legally enforcing marital contracts designed to guarantee cooperation in the allocation of domestic time (De Laat and Sevilla-Sanz, 2011; Rasul, 2008), partners could free-ride on each other's contributions.

Figure 2 Trends in fertility, female labor force participation, and gender division of domestic work. Note: Figure displays total fertility rate (TFR), female labor force participation (FLFP), and the men–women ratio of time in domestic work (includes housework and childcare). Given that it is not possible to restrict the sample to households with children in the MTUS time series, we include all individuals aged 20–59 years, unlike the numbers reported in **Table 1**. Given that parenthood exacerbates gender specialization in domestic work, we can consider the time estimates above a bit conservative. Sources: OECD, 2012. OECD Family Database, OECD, Paris. www.oecd.org/social/family/database and MTUS, Jonathan Gershuny and Kimberly Fisher, with Evrim Altintas, Alyssa Borkosky, Anita Bortnik, Donna Dosman, Cara Fedick, Tyler Frederick, Anne H. Gauthier, Sally Jones, Jiweon Jun, Aaron Lai, Qianhan Lin, Tingting Lu, Fiona Lui, Leslie MacRae, Berenice Monna, José Ignacio Giménez Nadal, Monica Pauls, Cori Pawlak, Andrew Shipley, Cecilia Tinonin, Nuno Torres, Charlemaigne Victorino, and Oiching Yeung, 2012. Multinational Time Use Study, Versions World 5.5.3, 5.80, and 6.0 (released October 2012). Centre for Time Use Research, University of Oxford, United Kingdom. www.timeuse.org/mtus/.

Questions also remain on the relative importance of cultural and social norms vis-à-vis institutional context and policy intervention. Distinguishing between norms and institutions is empirically hard, given the simultaneity of both processes; and findings so far are mixed. Some studies have used immigrants to isolate the effect of social norms (from the country of origin) from institutional factors (at destination), finding that characteristics of the country of origin play an important role in determining women's employment behavior (Fernández and Fogli, 2006; Fogli and Fernández, 2009). In contrast, Klüsener et al. (2013) exploited a natural experiment in a culturally and linguistically German region in Belgium (two countries with diverse fertility outcomes), to find that institutional and policy circumstances trump cultural norms when predicting fertility.

The descriptive associations presented in this article also deserve further investigation. From our comparison across countries of recent trends in fertility and in the gender distribution of time in domestic activities, we advanced a tentative hypothesis: that there is a threshold level of domestic gender equity that needs to be crossed to trigger a process of fertility recovery in industrialized nations. Testing whether this threshold is similar across countries, or whether it is shaped by cultural or institutional factors, might constitute a fruitful avenue for future research. To that end, time diary data provide an invaluable resource. Important time diary resources are already available, such as the MTUS (2012) with more countries and waves being included and more data being harmonized every year, both from developed and developing countries. Such efforts should be continued and more widely used by researchers in the behavioral and social sciences.

Gender: Anthropological Aspects

This article is a revision of the previous edition article by B. Aretxaga, volume 9, pp. 5915–5920, © 2001, Elsevier Ltd.

Abstract

Having moved from the margins of anthropology to a position of centrality in the discipline, studies of gender now tend to focus on ethnographic and historical particularities and on interrelationships between gender and other aspects of society and culture, including prominently language and law, health and reproduction, religion, violence, and gender identity as a situated and performative accomplishment. The role of gender under conditions of regional and world historical change, such as postcolonial and postsocialist transformations, is a significant organizing principle in these lines of inquiry.

Conceptualizing Gender in the Postmodern Era

The term *gender*, to address and acknowledge the concepts of female and male as constructed by specific societies, entered into widespread anthropological use in the 1980s. Although a select few female anthropologists in the first half of the twentieth century conducted pioneering field research and published studies of women in a wide range of societies, it was not until the 1970s that feminist anthropologists established women as an independent topic. This newly established interest led to edited volumes in the 1980s linking gender with classic anthropological topics such as colonization, kinship, language, and regional studies. Studies explored women's reproductive lives, their role in shaping and maintaining kinship relations and their participation in the new transnational labor market; the relation of gender to colonialism and nationalism became a primary topic, and class and ethnic differences were identified.

A transitional decade for gender studies, the 1980s shifted the direction of research from recognizing gender differences and providing explanations to showing the effects of social and political systems on gender relations, mediated by discourse.

Crossing a Threshold to a New Configuration

From the marginal position it occupied in the early years, gender studies claimed a space at the dynamic center of anthropology in the 1990s. More than a continuation, this centrality represents the crossing of a threshold to a position that recognizes gender as foundational to every set of social and political circumstances. Attributed in part to the United Nations decade for women (1975–85) and the Beijing conference in 1995, epistemological changes were also occurring within anthropology. This repositioning can best be described as a *reconfiguration*.

In contrast to the view of gender as a static, stable category, studies of the 1990s and 2000s have recognized that 'gender' is a process, a situated accomplishment in the conduct of social life, and further, that multiple variations of the concept of gender may exist within one culture as well as across cultures. Like anthropologists generally, those who focus on gender have responded to the social and political developments of the late twentieth century with engagement and activism in the effort to link global and transnational movements to the local and new knowledge to emerging situations. Consequently, relevance to the conditions and events of contemporary social and political life has become an important measure, an indicator of valuable work in the anthropology of gender.

Theoretical approaches that shape the analytical perspectives of twenty-first century scholars are sometimes imported from the larger domain of social theory or from intellectual movements in the field of social and behavioral sciences. Rather than relying upon theories that strive for universality, or those of Western feminism that have been much criticized, research in the 2000s delves into complexity, recognizing the interaction of continuity with modernity in situations often characterized by ambiguity and contingency, leading to a focus on specific locations, people, and circumstances, in contrast to the more general term, *culture*.

Erasing Boundaries and Fusing Categories

Evidence of the centrality of gender to anthropology can be found in the sections on gender that appear in sociocultural textbooks, often coupled with 'sex' or 'sexuality.' Also important are the anthologies devoted solely to articles on gender as studied by anthropologists. The major anthropological journals publish the most recent gender research, and ethnographic studies featuring gender continue to occupy a prominent place in the catalogs of scholarly presses.

Conceptually characteristic of the new configuration is the erasure of boundaries separating disciplines and a fusing of categories and terms. For example, the long-separated terms, *sex* and *gender*, have now been reunited (McConnell-Ginet, 2011) while gender is combined with numerous other terms relevant to a topic such as identity, politics, Islam, and land (Hoffman, 2008). Some authors conflate the terms *feminism* and *gender* while others argue for a distinction, stating that the goal of *feminism* is the identification of inequality and the improvement of women's position whereas *gender* encompasses both females and males and their interaction as well as the production of knowledge related to these concepts. However, in many parts of Africa, the Middle East, and Asia, *feminism* continues to be a contested concept associated with the West,

whereas *gender* has largely been acknowledged as relevant and studies increased in the past decade.

Taking a broad overview of gender studies reveals a radical change in the division of labor among disciplines. Those that have conventionally studied domestic societies or restricted themselves to the past have now extended their research to non-Western societies and/or to the present. Working alongside anthropologists are sociologists, historians, political scientists, and scholars from the newer fields of Women's Studies or Gender Studies and area studies departments. The results of this common interest have brought gender scholars together and demonstrated the value of collaboration. The transdisciplinary approach has been a principled effort to transcend the biases of the various Western disciplines. The outcome has been conferences and exchanges and a rich body of edited volumes on gender: Joseph (2000), Lutkehaus and Roscoe (1995), Lamphere (1997), and Cohen et al. (1996).

Global Developments: Region, Revolution, and Religion

In regions of the world in transition studies of gender have flourished, some of which address large-scale social change, others that identify a regional focus, and some that have religion as the basis of the work. Researchers working in these areas select for ethnographic specificity and the identification of key variables rather than generalization, a scholarly strategy that tends to erase gender differences and plural perspectives on any subject.

A major development in addition to the twenty-first century turn to regions and religion is the prevalence of scholars who are native to the region or members of the religion, bringing insider and outsider views together, and, at times, into question. Equally significant are the numerous border intellectuals, those who occupy an interstitial cultural space, allowing them to speak with freedom from any national or cultural perspective.

Although anthropological studies in Eastern Europe are new since the fall of the Soviet Union, a rich body of research has been undertaken. Gender issues are a high priority for a group of scholars from several disciplines. Anthropologists have emphasized the importance of recognizing continuities with the past at the same time noting that the presence of the West in the region is indispensable today. These scholars have argued for a theoretical framework based on reciprocal effects: states produce ideologies and policies that circumscribe relations between men and women, but ideas about gender differences also shape the construction of the state.

Moreover, a gendered perspective highlights important aspects of the postsocialist transformations that have been taken for granted. Although the independent states in this region were once a part of the regime of state socialism, they have emerged with many different concepts about gender relations. Among the issues of greatest concern to gender scholars is the question of rights and policies relating to reproduction in the new independent or newly unified states: the discourse and policies surrounding reproductive rights (abortion, sterilization, sexuality), although issues of labor, class, and identity are also of concern (Gal and Kligman, 2000).

Muslim women were introduced to anthropologists in the West by Elizabeth Warnock Fernea with her pathbreaking book in 1965. Within the space of Fernea's lifetime, women in Muslim societies have captivated the attention of scholars, Muslim and non-Muslim alike. Gender in the Middle East and women in Muslim societies became relevant topics in the 1980s (Abu-Lughod, 1986), to extend in the 2000s from Africa to Central Asia, and taking account of the construction of gender in circumstances as different as neocolonial modernity and Islamic fundamentalism. Recognition of the scale of the subject is the six-volume *Encyclopedia of Women and Islamic Cultures* (Joseph, 2003–2008).

As Muslim women have so often been represented as the 'Other,' a practice revived since 9/11, studies focused on gender in Islam have sought to unravel the effects of global change and to unmask the discursive practices through which the image of the repressed woman has been portrayed. Research has centered on Muslim women's political involvement (through mothering practices, religious piety, and social activism), the gendering of citizenship, the legal privileging of males, religious nationalism, and other issues that result in inequities.

As gender scholars have argued in the past, women are often made into symbolic markers of the nation, and, indeed, research on Middle Eastern societies show that when women are made into symbolic markers, institutions and processes of the nation subsidize efforts to ensure control over reproduction, maternal rights, productivity, and wealth. The symbolic equation of women with the nation often leads to subordination of actual women through calls for the preservation of tradition, the family, codes of ethic, values, and other claims. Of particular interest, these studies have shown that patriarchy weaves together civil society, the state, marketing, and the family.

Two specific locations deserve comment due to events of consequence. In Turkey, a country where the dominant religion is Islam, gender has emerged as a fixture in national discourse due to major changes in the country. Since independence in 1923, Turkey has been defined as a secular country, but a change in government has allowed major shifts with regard to the public expression of religion. The resulting controversies frequently focus on gender and on the wearing of 'headscarves' by Muslim women. The headscarves function as an icon of the larger discussion on the relationship of women and religion, a topic taken up by numerous scholars. In North Africa, the Arab Spring has created upheaval and uncertainty. While most questions about the future remain unanswered, anthropologists have already begun documenting the experience, building on a significant body of scholarship on the women's movement in Egypt especially. Of renewed interest also is the life of Um Kulthum, the singer who became the national symbol of Egyptian independence in the colonial era.

Among Africanists, gender and the related concepts – feminism, women, masculinity – have generated a significant body of literature that characteristically addresses colonialism and postcolonialism in Africa or challenges the domination of Western paradigms on gender. Especially significant in the past two decades, the number of scholars from the African continent has increased notably. Some have degrees from African universities, others from England or France, as well as the United States, and they hold positions in agencies as well as universities. Research on gender is being published in Africa

and in Europe and also by the development agencies that publish in-house reports. Consequently, the literature on gender in Africa is widely dispersed and issues discussed among one set of scholars do not necessarily reach into another set of scholarly discussions.

Central to the controversies among gender scholars are models developed by scholars and activists in the West, considered not applicable in Africa due to the major differences between African societies and Western ones. Kinship systems are radically different as are religions, political organizations, and economies. Coupled with the powerful effects of colonialism and modernity on African societies that intensified gender hierarchy and female subordination, these differences have been highlighted and revised agendas formulated for research. The most frequently cited example of difference concerns the family and the position of the individual person. In the West, individual autonomy is the goal, and the nuclear family is the fundamental social unit, emphasizing the dichotomy – female and male. In contrast, the African family model has been described as a corporate group – one based on lineage and clan through which members maintain their cultural forms and ties, rather than loosen or sever them, making contributions and receiving benefits. Western models tend to create fixed categories whereas African ones are quite fluid, making adaptation, substitution, and transformation possible. Gender and sexuality are complex concepts, embedded in all dimensions of social life in most African societies. Abstract as well as material, they have rich metaphorical capacities, adding layers of significance to social life, which often remain opaque to outsiders.

Yet another difference concerns the goals of women. In the many different societies of Africa, women are struggling to achieve gender equity, but that does not mean that women want to be similar to men; alternatively, African women value their unique female traits and styles (particularly dress), their economic activities, and their role as mothers, all together.

The past two decades have witnessed a move among anthropologists well beyond the paradigms of the previous century, taking account of the complexities of African gender systems. At the forefront have been studies demonstrating that gender is at the core of African cultural models. Of importance has been the recognition that high-status females in positions of leadership (both political and religious), usually paralleling those of males in a dual gender system, characterize a great many African societies (Kaplan, 1997). Due to colonialism, their power was reduced considerably in many societies though Asante queen mothers in Ghana remain strong. Equally relevant is women's participation in and contribution to the economy, a factor that links the household to the larger entities of community, clan, and local political systems (Mikell, 1997). Developed in the 2000s, research has shown that African economic strategies operate within a plurality of different systems of value; many systems of exchange are regulated by popular convention rather than the formal systems of the state. Pointing to the effectiveness of popular economic activity, it has been argued that viewing formal and popular economic systems as a single configuration would advance our understanding of global economic realities, a consideration that would count women's contribution legitimate (Guyer, 2004).

Major developments in social and political theory have resulted in a rich body of gender studies, some of which feature women speaking for themselves (Stoeltje, 2009) while others have directed attention to the symbolic, religious, and economic value women place on cloth as it circulates, is displayed, or collected; yet another group of scholars has focused on fashion, dress, and clothing, while anthropologists have also focused on the female body as symbolic communication – the meaning of naked and nude, as vehicle for spirits, and the body as bathed, revealing one's moral and civic personhood (Masquelier, 2005). Important also are studies addressing the relation between women and the state, the impact of HIV/AIDS on women (whether wives or sex workers), health and reproduction, women's resistance to authorities (wicked women), and gender and the law (state law and legal pluralism).

Emergent Syntheses and Twenty-First Century Configurations

Identity, Sexuality, and Subjectivity

Not surprisingly, issues of identity have proven to be longstanding in anthropology because identity becomes a conscious feature when others are perceived as different. In recent years, sexuality, subjectivity, and gender are frequently conflated with identity and used to address issues of belonging, recognition, and legitimation. While the concept of subjectivity is broadly applied by scholars, recent work in anthropology on subjectivity argues that gender is both the embodiment of the symbolic and the expression of freedom (Moore, 2007).

As one gendered feature of identity, masculinity studies have explored how manhood is constituted, especially through initiation rites, and how it is performed and evaluated in societies in every continent. Noting the connection between masculinity and subjectivity, scholars have observed competing notions of masculinitiy within groups and different expectations of masculinity for different age groups.

Questions of sexual orientation are intimately associated with subjectivity and identity: gay and lesbian, transexual, two spirit, third social gender, and others. Anthropological research on sexual subjectivities has been refined theoretically in the past two decades and now takes non-Western gay and lesbian subjectivities as legitimate forms of selfhood and links up with research on sex work and trafficking (Boellstorff, 2007). Research on subjectivities in the United States previously overlooked includes the rural gay and lesbian youth in the Midwest of the United States (Gray, 2009) and gay fatherhood (Lewin, 2009). Rediscovered are the two-spirit people of Native American groups (earlier labeled *berdache*) who have the potential to recognize gender diversity (Jacobs, et al., 1997).

Turning to Southeast Asia, a region where alternative sexualities were tolerated until the twentieth century, when they were criminalized, a historical perspective shows a region known for its wide array of legitimate sexual roles and practices. Research employing the concept of pluralism demonstrates that the dynamics of gender and sexuality are deeply imbricated in the politics of race, ethnicity, religion, and class (Peletz, 2009). Anthropologists are also documenting issues of gender

identity in other Asian countries, including the emergence of gays and lesbians in India, and their legitimation by a high court in New Delhi, questions of being gay and Muslim in Indonesia, and the public discourse about sex and sexuality in China. In the neighboring Pacific island of Tonga, gender, identity, and subjectivity are publicly performed, negotiated, and displayed through beauty pageants: the Miss Heilala contest for young women and the Miss Galaxy "other pageant" that showcases transgender roles (Besnier, 2011).

Gender as an Analytic Category

Among the most significant but subtle theoretical developments in the past decade has been the recognition of gender as a resource for shaping phenomena beyond recognizable gender categories. Although lacking a specific name, this approach represents gender as an analytical category. Tracing it as it diffuses throughout dimensions of social life and domains of policy and practice at the cultural, national, or global level, it penetrates aspects of social relations otherwise opaque, including national and international events and movements. A widespread but seldom recognized practice involves the construction of knowledge in any institution or nation-state whereby one kind of knowledge obstructs another. Research has analyzed the means by which the authority of professional knowledge elides gendered knowledge in specific instances, raising the question, when does attention to gender difference emerge (Boyer, 2006).

As an analytic category, gender can shape the organization of specific cultures as well, affecting social relations, ritual, and identity. For the Kabre of Togo, the fluid concept of gender permeates both practical and symbolic life, organizing the material arrangement of houses, and courtyards, designing initiation, defining clans, naming the seasons, and ultimately determining the burial site of the individual. Gender is the construct that balances marriage, kinship, nurturance, and rites of passage, and organizes rituals that bring about the changing of seasons, including powerful gendered symbols. As the dynamic force diffused through all domains of Kabre life, gender provides the symbolic map for the construction and interpretation of the cosmological as well as the social (Piot, 1999).

Health and Healing, Disability, and Disease

Among the specific areas that have attracted gender scholars in the 2000s is the domain of health, a topic of increasing concern in the twenty-first century in every society. Women are centrally engaged in matters of health, first because of childbirth and second because of the care and nurture of children in most societies. Sexuality and sexual behavior of males and females, including sex workers and sexual relations within marriage, all have drawn the attention of anthropologists because of the crisis around HIV/AIDS. These particular issues and closely related ones have risen to prominence due to wars and conflict, poverty, the spread of disease, and government refusal to respond to these conditions (Briggs, 2004), yet in some instances women have organized to confront the failures of the government (Susser, 2009). At the same time, women healers continue to practice their art in some societies. Among the Tuareg, for example, the medicine women who have expertise with herbs and natural cures continue to treat the female population, also providing psychological support (Rasmussen, 2006).

Disability, too, creates gendered responses, one of which is the phenomenon of male attraction to females with disabilities (such males are known as *devotees*). Approaching the problem of disability on a national/global scale, scholars have found it to be a widespread condition in the former Soviet Union, and rampant in war zones.

Gender and the Dynamics of Violence

Theoretical perspectives have developed around topics that have made headlines in the twenty-first century. Violence dominates in that news. Consequently, scholars of the past two decades have been in conversation around that subject, developing theories to account for the dynamics of violence and its relationship to state power as well as domestic violence that can disrupt and unmake the world of those who inhabit the space. As most anthropologists have argued persuasively, violence links to larger social and political ideologies and understandings that connect the national to the domestic and empires to colonies, with the category of gender as essential for understanding that connection which is found to reside in foundational stories about the nation-state.

Within liberal philosophy, the emphasis on giving life to the nation and dying for the nation are powerful because they seem to normalize violence as part of gendered belonging to the nation-state. The implications of this position are that men should be ready to bear arms and to die for the nation and that women's reproduction rightly belongs to the state (Das, 2008; Aretxaga, 1997). More specific studies have addressed gender violence in context, revealing underlying ideologies that legitimate the many forms resulting in violence. The topic of one such study, the women's role in the Dirty Protest at the Armagh prison (Ireland), linked the shocking power of the women's primordial symbols with the domains of prison violence, colonial history, and gender discourse and argued that gender is an intrinsic component of violence (Aretxaga, 1995).

Yet another specific study is located in a South African neighborhood (where unemployment rises to 30%). Drawing on gender theory focused on males, this research found that young men who join gangs and engage in acts of violence are shaped by values anchored in the ideology of masculinity that held sway during the apartheid era (Salo, 2006).

Advances in Language, Law, and Performance

Performance

Performance theory, in combination with ethnography, directs attention to gender issues and ideologies as they are enacted for an audience. Whether the more individualized performance that focuses on the spoken word or song or a large-scale event with many participants (ritual, festival, markets, sports, and drama), these events capture the imagination with a shift to a time, place, and action set apart from the mundane and quotidian present. As developed within anthropology, a performance approach identifies what activities women and

men are engaged in before an audience as an expression of their preoccupations and commentaries on social life. Performance has the potential to enact resistance, memory, irony, satire, devotion, competition, transformation, or other forms. Considered from two perspectives – one in which the verbal is the focus and the other, a cultural performance – these are often integrated.

Studies concentrating on women as performers within gendered societies around the globe have identified rich repertoires of female genres and performance spaces. Moreover, these studies have proven to yield subtle understandings of how women are inscribing new values into their lives in situations of rapid social transformations. In markets in Morocco, for example, women's presence has increased and with that they have created new roles and carved out unique discursive domains, mixing categories and revoicing expressive forms (Kapchan, 1996). Equally significant, Chicanas using a performance approach have taken a critical stance toward the concept of tradition, exploring how women musicians and performers in *charreada* (Mexican rodeo) understand the power and politics inherent in performing (Najera-Ramirez and Cantu, 2002).

Performances involving males as well as females reveal relations between the two, often challenging, contesting, and negotiating those roles. During annual ritual/festival events, women and men in societies of the South Pacific engage in clowning performances, reversing gender roles, and in the process providing cultural critique on gender roles (Mitchell, 1992).

In South India, female and male performers on the Tamil stage (called Special Drama) have provided sophisticated insight into their gendered positions in society and how they respond with a range of verbal skills (Seizer, 2005).

Viewing gender as performed permits the female to emerge as subject, and both female and male to perform and/or explore or transform roles, creating an opportunity for reflection and critique. Above all, performers experience achievement, accompanied by varying degrees of power and a space filled with promise.

Language and Law

In the 1970s and 1980s, linguistic anthropologists tackled the issues of difference in the speech of females and males through ethnographic studies in societies around the world, including the United States. In almost every instance, significant inequities were found, leading to new questions concerning speaking and silence. Studies of language use in relation to gender continued to captivate scholars' interest in the 1980s, who observed that men performed roles and genres associated with political authority and public settings, while women controlled other genres and settings such as lullabies and stylized mourning. A major issue was whether differences in language could be considered a women's language and a men's language as some scholars proposed; further studies argued that language and social status could be correlated, and features of language use considered to be characteristic of women were also used by men of low status; though women used this language, known as 'powerless language,' men of low status also used it. Other studies showed the importance of context and how the organization of gender behavior (men's groups, women's talk) affected language; an additional variable showed the use of 'women's language' as a communicative strategy.

The next two decades elaborated on these questions, considering who has access to speaking in any situation. Studies showed that the silencing of women's voices generally rests on an underlying ideology that endows women's speech with a negative evaluation, expressed through conversational strategies that discourage women's participation. Theories of the social use of language encouraged the analysis of how social relations are created, negotiated, or denied through language. Noting that some linguistic strategies and genres are more highly valued and carry more authority than others, and these practices occur within institutions where speakers impose their definitions of events, peoples, and actions on others, they have been labeled with the term, *symbolic domination* (Gal, 2006). Consequently, it was concluded that language serves as an index of position and of ideology. Exploration of the links between gender, language, and power further revealed the greatest impact to be in power's ability to impose its visions of reality, inscribed in language and enacted through interaction.

Ethnographic attention to women's voices in female linguistic genres from different classes, ethnic groups and societies found a wide range of genres, some of which were used to express opposition to the dominant vision of reality. An example from North India documented Hindu rural women who perform songs at women's rituals and tell stories explicating them through which they express poetic resistance to structures of power (Raheja and Gold, 1994). Shifting to the Warao of Venezuela and comparing male and female speech genres, it has been shown that the only public genre accessible to women is ritual wailing, performed at funerals; through it, however, women unmask hierarchies that sustain the power of the postcolonial institutions and the nation-state; in contrast men's gossip serves as a contested space in which women's discourse is delegitimized and men's is legitimized (Briggs, 1992).

Little known until recently is an instance of women's language. In China, literacy and language were linked together as a communicative form for peasant women in Jiangyong County during the late imperial period. This gender-specific language was known as *nushu* (female writing). Associated also with a special ritual friendship, these sisterhood communities often failed to survive after marriage due to village exogamy (Liu, 2004).

Intertwined with the analysis of language is the anthropology of law; whether considered indigenous, customary, or modern, legal systems employ language, translating everyday categories into legal language to effect powerful changes. It will be apparent in any court or legal proceeding that a legal system utilizes discursive practices embodying concepts of power consistent with the gender ideologies that characterize specific cultures' assumptions about gender. Characteristic of all legal systems also is status, embodied in the roles occupied by individuals in a court or other legal setting. The speech in legal settings, of all individuals, will reflect status and, often, a position on gender.

Although anthropologists initially analyzed language in legal settings in small-scale societies, by the 1990s, research included a focus on legal systems in the United States and other

Western-style legal systems. These included the language of judges, lawyers, witnesses, and litigants, and a focus on gender. Moreover, anthropologists working in countries with relatively new state legal systems began looking at gender as defined and exercised by the state and the courts in those countries. In spite of the claims of modern legal systems, the courts in postcolonial settings often require lengthy wait times and high fees, proving not helpful to those with low incomes. Often knowledge of gender and/or women in relationship to the state has been located in the area of family law, the legal domain that has the most direct influence on women, men, and children. Family law has been criticized because the colonial powers who created it often placed religion in the domain of family law. Religion-based family law divides the citizenry into separate legal communities which then exacerbates differences as it has in Egypt, and those differences are played out with women as the symbol standing for one religion or the other all too often. Furthermore, family law that incorporates religion becomes oppressive for women if the religious perspective privileges males.

Viewing women's speech in courts often proves to be the means by which we identify how much access women have to the law and what constraints women encounter in legal experiences. Studies of women in indigenous/customary courts as well as state courts have emphasized the importance of the links between social and legal identities and revealed the advantages and disadvantages women face in any legal system. For example, Swahili women in Kenya take their problems to an Islamic court where a generally sympathetic male judge (the kadi) hears their stories of marriage (Hirsch, 1998). In the customary courts of the Asante in Ghana, women, as well as men, speak for themselves, and queen mothers and their courts hear cases involving women. In other societies, however, women frequently encounter difficulties when dealing with either indigenous courts or modern ones (Stoeltje, 2002).

The effort to define women's rights as human rights has attracted legal anthropologists who have brought their skills to the subject to argue for the legitimation of women's rights and to pursue specific issues such as prostitution, the labor force, land rights, gender violence, sex trafficking, and other issues that impact the lives of women. These topics are intertwined with global networks, international law, and the United Nations, leading anthropologists engaged in gender studies into these territories (Merry, 2006).

Abstract

The term gender first appears in psychological discourse of the 1950s as a concept designed to overcome biological determinism. The constructionist approach of conceptualizing sex as a biological distinction and gender as a cultural category became central during the 1970s for the feminist aim of transforming disciplinary paradigms and power relations. The critique of ahistorical and universalizing accounts of gender influenced its several reformulations, most notably a deconstructive approach defining sex as a social construct. This article illustrates the manner in which disciplines were gendered, the most salient changes implemented, and the ways in which epistemic contestations were translated into practical analysis.

Introduction

The history of the nongrammatical use of the term gender starts with an article by psychologist and sexologist John Money from 1955 in which the concept of 'gender role' was introduced (Haig, 2004). Influenced by the Parsons' concept of the 'sex role' and Freudian psychoanalysis, Money defined 'gender role' as a term "used to signify all those things that a person says or does to disclose himself or herself as having the status of boy or man, girl or woman, respectively. It includes, but it is not restricted to sexuality in the sense of eroticism" (Money, 1955: 254). In this psychological study of hermaphroditic patients manifesting somatic 'ambisexual anomalies,' Money observed how the variables defining one's sex (including assigned sex and sex of rearing, external genital morphology, internal accessory reproductive structures, secondary sexual characteristics, as well as hormonal , gonadal, and chromosomal sex) relate to one's gender role and orientation as male or female. The study suggested as the prognosticator of a person's gender role, not gonadal and hormonal sex or internal accessory organs as expected, but assigned sex and sex of rearing. By concluding that one's orientation as male or female does not have an "innate, instinctive basis" (Money, 1955: p. 308) and that the dichotomy male/female needs to be reconsidered, the article surpassed the dominant hereditary doctrine and pointed out the strong influence of the social environment on sexual behavior.

Based on a survey of academic articles from 1945 to 2001, Haig (2004) found that authors using gender in the 1960s seem to derive the term from Money. These authors were mostly publishing in psychological journals and were dealing with phenomena that did not conform with the heteronormative matrix (hermaphrodites, transvestites, homosexuals, etc.). The concept was further developed by psychoanalyst Robert J. Stoller (1964) by endorsing the term 'gender identity,' which he defined as the "sense of knowing to which sex one belongs, that is, the awareness 'I am a male' or 'I am a female'" (Stoller, 1964: p. 220). Similar to other early writings on gender, these articles were influenced by the psychoanalytical school of thought, which has played a crucial role in suggesting that 'natural' attributes of sex are in fact the effect of physic representation of gender (Elam, 2000: p. 169).

However, the widespread use of the term gender and its rise in the social sciences is connected with the feminist adoption of the term. While Simone de Beauvoir already provided the theoretical framework for the sex/gender distinction in her 1949 classic *The Second Sex* (de Beauvoir, 1949), a closer elaboration of this relation was delayed until the 1970s (Millet, 1970; Oakley, 1972; Rubin, 1975). An analysis of articles in the Web of Science database, which address the topic of gender, reveals a steady rise across social science disciplines such as psychology, history, political science, sociology, and economics from the beginning of the 1980s (see **Figure 1**).

By the mid-1980s gender became the central category of the feminist thought and has influenced the formation of new study areas including women's; gender; men's; lesbian, gay, bisexual, and transgender (LGBT); and queer studies (as well as studies of masculinity/femininity).

Gender as a Central Category

Feminist thought of the 1970s and part of the 1980s predominantly conceptualized sex as biologically given in contrast to the culturally and socially constructed gender. Judith Squires (2000) labeled this a 'constructionist approach' to gender theory. This differentiation became extremely theoretically influential and politically significant because it enabled feminists to contest the domination of concepts such as 'sex' or 'sexual difference' that were closely related to 'biological determinism.' The latter signifies the belief that anatomy dictates the disposition and social role of the individual and that differences between women and men (as binary and opposing sexes) are biologically rooted and therefore immutable and resistant to change (Hawkesworth, 2013; Nicholson, 1994). The rejection of biological determinism and the accompanying constructionist perspective on gender have their origins in psychology and historically overlap with, and were partly empowered by, the broader epistemological shift to poststructuralism and criticisms of empiricism (Scott, 1986). The viewpoint of understanding gender as the social institutionalization of sexual difference (Moller Okin, 1998: p. 116) was at the time a crucial part of the critical and emancipatory idea that women's scholarship and activism could transform disciplinary paradigms

Figure 1 Trends in coverage of gender in social sciences.

(Scott, 1986) and power relations in society. In that sense, a thorough understanding of the beginnings and significance – as well as the discontents – of the constructionist approach to gender is inseparable from the study of feminist positions on scientific knowledge (*see* Feminist Research and Social Work; Situated Knowledge, Feminist and Science and Technology Studies Perspectives) and the history of women's movements and activism.

Structuralist studies in the feminist tradition from the 1970s reflected the need to analyze the mechanisms of social forces and power relations that construct gender identities. Presented by some of the landmark studies of second-wave feminist theory, each of them emphasized different aspects of social relations such as reproduction (Firestone, 1970; Rubin, 1975), production (Eisenstein, 1979), mothering and caring (Chodorow, 1978; Gilligan, 1982), or sexuality (MacKinnon, 1983; Millett, 1970) as the ones crucial for the reproduction and perpetuation of gender inequalities. Despite their influence, these readings were criticized, among other things, on the account of gender conceptualization. Firstly, the analyses relied on monocausal explanations of inequality (Moller Okin, 1998) while disregarding the effect of a broader socioeconomic and political context. Secondly, it produced ahistorical and universalizing accounts of gender (Scott, 1986) that were possible due to the widespread acceptance of 'biological foundationalism' – an understanding according to which gender is a matter of cultural specificity, while sex is treated as a cross-cultural and cross-historical commonality (Nicholson, 1994). In other words, the representatives of the constructionist approach took for granted the idea that sex is a stable, biological, i.e., materially given, category upon which gender as a matter of culture and character is constructed. Thirdly, issues of race, class, and ethnicity were neglected. This created a sense of false unity combined of otherwise conflicting and heterogeneous elements while masking the privileges of the white, middle-class, and heterosexual women (Hawkesworth, 2013).

This critique has influenced a twofold conceptual reformulation. Firstly, the scholars answered the objections of ahistorical and universalizing tendencies by providing complex and multifaceted accounts of gender and by incorporating intersecting impacts of race, ethnicity, class, sexuality, disability, etc. The latter was most prominently elaborated in the intersectionality theory (*see* Intersectionality), which through its multiperspectivity challenged the domination of the standpoint theory characteristic for the second-wave feminist scholarship (*see* Standpoint Theory, in Science). Yet, many of them seem to have preserved the assumption of the male/female gender binary. The literature refers in various terms to this conceptual move, as a shift from theorizing single accounts of social structures to multiple ones (Squires, 2000), a turn from difference feminism based on a belief in universal commonalities among women to diversity feminism (Dietz, 2003), or as a shift from identity to difference feminism.

The second part of the reformulation was analytically more challenging and the epistemic contestations it has caused persist until today. More precisely, under the influence of contributions that read genealogies of power and histories of sexuality differently (such as Foucault's (1976) and Laqueur's (1990)), combined with refined insights from literary theory, psychoanalysis, and postmodern theories, feminist theoreticians endorsed a new approach to sex and gender. This approach – whose most prominent advocate was Judith Butler (1990) – deconstructed the sex/gender binary, conceptualizing sex itself a social construct. Furthermore, the sex/gender relation based on a corresponding material/ideological framework is being reversed in the claim that gender performativity produces the sex (Butler, 1990). In a similar vein, Suzanne Kessler (1990), in her essay "Medical Construction of Gender," suggests the "backward" logic in sex/gender relation. When being confronted with the infants of ambiguous genital morphology, medical staff will be guided with the culturally conditioned image of gender in an attempt to attach the assumed 'natural' sex. Consequently, sex is being observed no longer as a biological category that precedes gender as a cultural category, but as a relational construction that requires a shift from a material to a linguistic, discursive (Squires, 2000), or symbolic understanding (Dietz, 2003).

The deconstructive turn, indicating the beginning of the so-called third-wave feminism, challenged the uniform existence of the subject of feminism, i.e., the 'Woman' suggesting instead multiplication and diversity of sex/gender combinations (Elam, 2000: p. 180), and called the (im)possibility of the political act into question. This has turned the direction of feminism and found its reflection in the split between feminist theory and feminist activism, within the theory itself (see Benhabib et al., 1995), and left the question of the appropriate methodology to operationalize these challenging theoretical insights open. Gradually, understandings of gender proliferated and theoretical approaches nowadays often reflect negotiations, as Mary Dietz (2003) labels it, between difference, diversity, and deconstruction feminism.

Gendering Categories

The majority of what was described up until now refers to fields where gender played a central role, such as feminist theory or women studies. At this point it is worth clarifying that all theory referring to gender is not necessarily feminist, while all feminist theory centers significantly or even exclusively on gender (Saltzman, 2006). The reason for the departure of gender studies from feminism can be found in the role that gender as analytical category played in gaining academic legitimacy of women's scholarship in the 1980s and the rise of popularity of gender studies within the past three decades. Instead of referring to 'women,' gender, similar to class or race, symbolized scientific neutrality and dissociation from politics of feminism (Scott, 1986). For that reason, it was accepted by those traditionally skeptical voices that perceived the activist and political agenda of feminism irreconcilable with scientific principles. Some of the consequences, as Scott (1986) and Lovenduski (1998) notice, are the often inconsistent and contradictory use of gender as a synonym for 'women' to ensure the political acceptability of the study and the fact that a great deal of gender studies no longer show explicit activist commitment to women's equality and social change, which causes predictable resentment by many feminist scholars.

Gendering categories, on the contrary, imply that the gender dimension was omitted in the 'classical' scientific disciplines resulting in hidden biases and distortions of standard conceptualizations. Accordingly, the process of gendering is required because research, methodology, and theory, which ignore gender as an analytical concept, are not good science (Goertz and Mazur, 2008: p. 6). This insight is particularly valuable because it overturns and contradicts the objection that feminism as political agenda does not have a place in value-free sciences. Gary Goertz and Amy Mazur (2008) define three distinct ways of gendering categories. The first way is to keep the name of the standard concept, but to change its substance by adding sex as an additional variable. Although many are skeptical of 'add-women-and-stir' approach, objecting that it has limited transformational potential, the addition of women in the regime classification of democracies or welfare states, for instance, shows the opposite. The second way of gendering categories is to 'adjectivize' the standard concept implying a new aspect to it, for instance, 'women's (social) movement.' The third way is to create a new concept as in the case of state feminism. As Goertz and Mazur (2008) rightfully warn, due to the changes in concepts, case selection can change and the results of previous analysis can be challenged. In other words, gendering has significant methodological and theoretical consequence that one needs to take into account.

Common paths and consequences of gendering categories across different disciplines encompass (at least) three levels. First, units of analysis were gendered, which in practice meant that women and women's experiences became a subject of inquiry. Second, the constructionist notion of sex/gender relation enabled a conceptual turn that facilitated the break with biological determinism and reductionism. Third, this has led to the proliferation of new areas of inquiry as well as to interdisciplinary approaches to methods and epistemologies. The paths through which gender as a category entered particular disciplines, and the ways in which theoretical contestations were translated into the analysis of some of the key concepts in disciplines of social and behavioral sciences, are elaborated below.

Psychology

The earliest contributions to the study of gender in psychology originated in the psychoanalytical tradition (Money, 1955; Stoller, 1964). The initial accounts of gender in psychology were critiqued on the similar basis to the studies of sexual difference, primarily for their ignorance and neglect of the social and political context of gender (Burr, 1998: p. 10). Although the impact of the social was recognized in some of the early studies (for instance, Money's previously described account of gender), the broader incorporation of the constructionist approach to gender in psychology that happened in the late 1960s and 1970s is most closely related with the second-wave feminist theory and activism (Chrisler and McCreary, 2010).

Starting with the Naomi Weisstein's (first published in 1963, reprinted in 1971) essay "Psychology Constructs the Female; or, The Fantasy Life of the Male Psychologist (With Some Attention to the Fantasies of His Friends, the Male Biologist and the Male Anthropologist)," feminist psychologists opened a range of questions and criticisms on the methodological and epistemological account of the discipline. Drawing on insights from feminist critique of science (Burr, 1998: p. 132; Chrisler and McCreary, 2010), they raised the awareness on how numerous studies used restricted samples in their research designs. The consequences were reported gender biases in theories of intelligence, learning, memory, thinking, identity, clinical diagnosis, and therapy (Crawford and Unger, 2000).

Additionally, the political role of psychology was questioned and its alleged neutrality challenged. By embracing the famous slogan 'the personal is political' feminist psychologists began to treat personal distress, not merely as a product of hormonal or other bodily disbalance, but as embedded in social, economic, and political inequalities (Worell, 2000). Consequently, the concept of gender enabled a shift from focusing on internal (individual) to external (structural) causes in psychological theory, research, and therapy.

The critique of early feminist works in psychology for providing monocausal, universalistic, and ahistorical accounts of gender (Scott, 1986; Nicholson, 1994) influenced the formation of the multicultural movement in psychology (Chrisler and McCreary, 2010) and integrative feminist psychology (Worell, 2000: p. 187). Nowadays, the predominant clashes are between essentialism and social constructionism (Worell, 2000), which correspond to the broader epistemological split related to diverging conceptualizations of gender.

Last, the concept of gender enabled the advent of new fields of psychological inquiry. The fields having gender as a central category include women's and feminist psychology, psychology of men and masculinity, and LGBT psychology. They originated in the 1970s and now have specialized organizations, conferences, and journals dedicated to these specific fields.

History

The first appearances of the term gender in academic historical discourse can be traced to early feminist writings that were primarily trying to establish narratives of women as legitimate voices within the discipline. Consequently, previously neglected areas of research such as private life, sexuality, and reproduction entered the area of historical inquiry. In the 1970s this was part of the idea that women's scholarship would transform the disciplinary paradigm and by including class, race, and gender would contribute to the creation of a 'new history' (including her-story) which would explain the organization of domination/subordination along these three axes. One of the classic texts for understating the role of gender in history is the essay *Gender: A Useful Category of Historical Analysis* by feminist historian Joan W. Scott (1986) in which she inaugurated a path-breaking debate in mainstream historical research (see Butler and Weed, 2011).

Based on an exhaustive overview of the available feminist scholarship, Scott argued that attempts to include gender, while remaining within traditional scientific frameworks, resulted in reductive or simplified generalizations that undermined the complexity of the analysis and stifled motivation for more substantive change. Furthermore, as gender was often used as a synonym for 'women' to assure scientific and political acceptability of the study, its analysis was restricted to areas traditionally related to women, leaving uncovered topics such as war, diplomacy, and high politics. Last, to the influential feminist studies of that time in the (radical) feminist, Marxist, and psychoanalytical traditions, Scott (1986) objected to the aforementioned ahistoricity of gender, to the reification of the sexual antagonism between men and women, as well as to the tendency to universalize the categories of male and female, which did not leave the space for historical specificity and variability. In order to develop gender as an analytical category, Scott, influenced by Foucault's genealogy of power and psychoanalysis, endorsed the refusal of the fixed and permanent quality of binary opposition and demanded a genuine historization and deconstruction of the terms of sexual difference in line with the criticism of Riley (1988) and Nicholson (1994). Almost 15 years later in her *Gender: Still a Useful Category of Analysis?*, Scott (2010) insists that gender is only useful when it goes beyond 'men' and 'women,' taken as fixed categories that only need to be described. Instead one needs to think critically about how these meanings are produced in relation to one another, how they are deployed and changed by focusing not on the roles assigned to women and men, but on the construction of sexual difference itself.

In conclusion, in the 1970s and the 1980s theoretical discussions on the category of gender went beyond the simple recognition of women's roles in history; they opened a range of questions about how, when, and why different roles have been assigned to sexes; how they varied across time and place; and under which circumstances were they enforced and constituted. Due to the criticism for ahistorical and universalizing accounts of gender, which implied a certain essence common to female identity regardless of time and place, the prevailing tendency in the contemporary mainstream gender and history is to incorporate deconstructive approaches while including multiple axes of specific sociohistorical circumstances that form gender identities.

Political Science

Drude Dahlerup (2010) reports the first use of gender within political science in the 1980s. Having in mind that the term dates back to the 1950s, the postponement reveals a lot about the discipline. Since the mid-1950s political science aspired to be established as an objective and value-neutral discipline adhering to behaviorist and positivistic principles. Within such a context it was first necessary (and possible) to introduce the variable of sex into the research. The concept of gender, on the other hand, was more difficult to incorporate into the research design. The reluctance to incorporate postmodern theories, as well as the preference of parsimonious models for hypothesis testing explains the discipline's animosity to the study of gender (Lovenduski, 1998: p. 352).

Nevertheless, gender entered the discipline due to the efforts of feminist scholars who recognized the practical and theoretical power inherent in the constructionist perspective to the gender/sex relation for dismantling some of the basic postulates of the discipline such as public/private divide.

According to Celis et al. (2013) the representative approaches of incorporating the conceptualization of gender into political scholarship can be systematized in the following ways. The first approach is based on gendering the classical units of analysis such as the citizen, the voter, parties, or states. In particular, sex is added as an additional variable or the analysis examines women as an afterthought (Goertz and Mazur, 2008), while asking traditional questions and using traditional methods. Characteristic for this direction is the strategy of inclusion defined by Squires (2000) as the one based on constructionist approach that aims to achieve equality in the political sphere by denaturalizing the presumption of sexual difference and eroding the link between sex and gender so that sex becomes irrelevant for the political engagement.

The second direction according to Celis et al. (2013) is the one focusing on arenas traditionally seen as being outside the domain of political science. Here the notion of 'the political' is being broadened and by studying women in their own terms, new areas of study are being introduced. According to Squires (2000), this approach predominantly uses the strategy of

reversal – one based on the constructionist approach to gender, but emphasizing how the form of engagement was influenced by gender while recognizing and revalorizing women's engagement.

The third approach is oriented toward the analysis of gender as a structure of social organization – study of gender regimes, gendered states, and institutions focusing on broader social patterns that reproduce gender inequalities (Celis et al., 2013). It questions not only the ways in which structures and institutions are gendered but also how the gendered subjects of politics are being produced (production of masculinities, femininities, and sexualities). Distinctive for this approach is the strategy of displacement (Squires, 2000) – based on the deconstructive approach to gender. As this directly touches the question of subjectivity as well as political and collective action, the epistemic contestations are translated and pertain to a number of theories and issues crucial for political science such as citizenship, representation, multiculturalism, democratic discourse, and political action (Dietz, 2003).

Sociology

The use of the term gender in sociology seems to have been pioneered by Ann Oakley in the early 1970s. By applying ideas about socialization, she sought to understand how gender is learned and how femininity and masculinity are socially constructed (Holmes, 2007: p. 42). In her later work on the sociology of housework, Oakley extended the theories on gender in order to explain the division of labor in the household and labor market segregation.

When providing systematization of gender in sociology, several conceptual levels are possible. This variety reflects, on the one hand, the discipline's multiparadigmatic character and, on the other hand, the theoretically challenging intersection of biological, social, psychological, and economical components inherent to the concept of gender. This explains why a significant number of the available overviews of gender in sociology provide either a general history of the concept or a history of feminist thought, which are connected, but still separate issues.

Amy Wharton's systematization (2005) of dominant frameworks within sociology to the study of gender as individualist, interactional, and institutional seems to reflectively circumvent this common slip, without reducing the complexity intrinsic to the matter. As one of the organizing principles of the social world, gender shapes the identities and behavioral dispositions of individuals, influences social interaction, and organizes social institutions (Wharton, 2005: p. 9).

Sociological scholarship on gender based on an individualistic approach would include, according to Wharton (2005), biosocial and evolutionary psychological perspectives, as well as theory and research on gender socialization and sexual differences that can be found both in psychology and in sociology. Although generally adopting a constructionist approach to gender, authors in this tradition conceptualized sex to be the basis for the development of gender that was treated as a stable set of personality characteristics.

A perspective challenging these assumptions offered an interaction-based perspective on gender instead. The seminal article representing this approach is "Doing Gender" by Candace West and Don H. Zimmerman from 1987. Largely inspired by the work of Erving Goffman, the authors approached the study of gender from an ethnomethodological tradition. West and Zimmerman (1987: p. 125) defined gender as a "routine accomplishment embedded in everyday interaction." In this way, the distinction between sex as a stable biologically given category (nature) and gender as culturally constructed (nurture) (*see* Nature/Nurture Controversy, History of) is openly contested, announcing the arrival of deconstructivist approach to gender in sociology. Besides the ethnomethodological tradition, interaction-based approach to gender is evident in status characteristics theory as well as in theory and research on homophily (Wharton, 2005).

The third approach presents the institutional perspective to gender. It encompasses a broad area of theory and research that treats gender as an organizing principle of social, economic, and cultural life. Accordingly, the practices and policies of organizations such as education systems, labor systems, health systems, work, sports, or family, to name only a few, are being studied.

Besides the well-developed women's studies, women's sociology, and feminist theory (see Smith, 1987), other developments within sociology related to gender include the development of men's studies and masculinity studies presented by Raewyn Connell's (1995) classic "Masculinities," as well as attempts to take into account variations within gender as a category and to accommodate complex intersections of gender with other categories.

Economy

A gendered perspective on economic processes reflected in the feminist critique of economy dates back to the nineteenth century (Bauhardt and Çağlar, 2010) and was present in feminist scholarship across various disciplines in the social sciences from 1970. However, feminist economics as a research direction within economics was institutionalized only in the early 1990s. Since then, the progress of the field and an overview of the major topics can be found in the classics of feminist economics *Beyond Economic Man: Feminist Theory and Economic* (1993) and *Feminist Economics Today: Beyond Economic Man* (2003) edited by Marianne A. Ferber and Julie A. Nelson. This direction is not a unified body of thought, as it was influenced by and stretches across all major streams of economic thought including neoclassical, Marxist, and institutionalist traditions.

The example of economics is especially illustrative of how far reaching the implications of gendering categories can be. In the 1970s under the influence of Marxism and socialism, second-wave feminists started questioning the role of the patriarchy within capitalist systems. By focusing on the category of work, they pointed out the significance of unpaid labor, done predominantly by women, for the maintenance of economic systems. Being perceived as marginal, private, and unproductive both by the neoclassical and by the Marxist tradition, unpaid housework was omitted from economic analysis. To illuminate its multidimensionality and above all gender-segregated nature, feminists adopted the notion of

social reproduction to cover biological reproduction and unpaid production at home (household maintenance, care work). The unjust distribution of the burden of social reproduction provoked the movement 'Wages for Housework' taking place in the mid-1970s in several countries of Europe and North America.

These insights disclosed the ways in which essentializing accounts of gender do not remain in the cultural and symbolic sphere, but are reflected in material consequences. More precisely, culturally defined norms determine the gender division of labor in the sphere of paid work (vertical and horizontal segregation) and between paid and unpaid work (women being disproportionally burdened by the housework). Where women's mass entrance on the labor market is concerned, gender-specific exploitation was reflected in disproportionally higher percentages of women in low-skill and low-paid occupations because of women's 'natural' capabilities for the job's performance implying no educational investment (Elson and Pearson, 1981). In contemporary labor relations, concepts such as the 'gender pay gap' and 'glass ceiling' indicate the globally documented difference in the earnings, i.e., positions acquired, and women continue to be more represented in outworking, contract and part-time labor, homework, and other forms of labor unprotected by labor regulations.

Conclusion

The first conceptualizations of gender as a socially and culturally constructed category have their roots in psychology from the mid-1950s. However, they became prominent mostly due to feminist scholars and activists from the 1970s. Additionally, the incorporation of gender as category into all major social and behavioral sciences was possible due to the broader poststructuralist turn, which influenced the characteristic feminist epistemological positioning and methodological framework. As they are historically varied, there are significant differences in the above-mentioned approaches to gender (biological determinism, constructionist (multi- or single structure), and deconstructive approach). Furthermore, favoring one or the other approach to gender differs across disciplines. For instance, while history or sociology seemed to be open toward deconstructive conceptualizations, others are more reserved and skeptical, such as political science, or appear to circumvent the issue, such as economics.

Irrespective of the degree of acceptance of the particular approach, based on this brief historical overview of the term's origins, it is possible to summarize its major contributions and ranges of significance. First, studies of gender, gender identities, and gender relations caused not only the proliferation of previously neglected areas of scientific inquiry within existing disciplines but also triggered the advent of new disciplines such as women's, gender, men's, LGBT, and queer studies. Second, the inclusion of gender as an analytical category and the gendering of scientific categories exposed the bias of scientific research that produced distorted results typically detrimental for women and thereby added to the broader debate on problems in the conduct of the social research. Consequently, women's experiences and voices were introduced into analysis, while gender contributed to the conceptual break with biological determinism and reductionism. At the same time, new areas of inquiry proliferated, which have challenged the epistemologies and methodologies of the scientific canon. Nevertheless, the reluctance on the part of academic disciplines to mainstream gender analysis, the irreconcilability of some parts of gender theory with feminist activism, as well as the question of the appropriate methodology to operationalize seemingly challenging theoretical insights are all issues that remain unsolved.

Abstract

The term 'gender' requires discussion, since different linguistic traditions describe gender phenomena using different terms. Moreover, while in many languages there is no dispute as to the number of genders, there are other languages where the question is far from straightforward. This requires consideration of the analytical problem of determining the number of genders in a given language. The central problem, however, is gender assignment, that is, the way in which the native speaker allots nouns to genders. Examination of languages from different families reveals that genders always have a semantic core, which may be biological sex, or animacy, with other features also having a role. In some languages nouns are assigned to genders solely on the basis of semantics, but in others this semantic information is supplemented by formal information, which may be morphological or phonological.

Gender is a remarkable category, pervasive in some languages, for instance in the Indo-European and Dravidian families, and lacking in others, as in the Uralic family. We start with a brief consideration of terms, then examine how the number of genders in a given language can be established. The number varies considerably: two and three genders are often found, four and five are not unusual, while Fula (a Niger-Kordofanian language) has around 20. Most attention will be given to the problem of how the speaker assigns nouns to genders. Gender systems may have sex as a component, as in languages with masculine and feminine genders; but equally sex may be irrelevant, as in the Algonquian languages where the distinction is between animate and inanimate. Finally we consider prospects for investigating the category further.

Terms

The defining characteristic of gender is agreement; a language has a gender system only if noun phrases headed by nouns of different types control different agreements. The evidence that nouns have gender in a given language thus lies outside the nouns themselves. There is no substantive difference between 'genders' and 'noun classes'; the different terms are merely the products of different linguistic traditions. For instance, we find systems with three genders, to which nouns are assigned by similar rules, in both Kannada (a Dravidian language) and in Godoberi (a Nakh-Daghestanian language). By tradition the first is said to have three genders, and the second three noun classes. We shall use the term 'gender' in both instances.

The Number of Genders

The approach to gender sketched in Sect. 1 is based on Zaliznjak's (1964) notion of 'agreement class.' Two nouns are in the same agreement class only if they take the same agreements under all conditions, that is if we control for other grammatical categories such as case and number. Conversely, if two nouns differ in their agreements when factors such as case and number are held constant, then they belong to two different agreement classes and it will normally be the case that they belong to two different genders. While in many languages there is no dispute as to the number of genders, there are other languages where the question is far from straightforward. In the case of Romanian there has been a lengthy debate. The analytical problem of determining the number of genders and the tests for deciding the gender of a given noun depends on separating out the classes into which nouns are divided (the controller genders) from the number of different genders marked on agreement targets (the target genders). Frequently the two match up, but in several languages they do not. A full treatment of the subject is not possible here; for a detailed account and extensive references see Corbett (1991).

Gender Assignment

We now ask how nouns are distributed over the genders of a given language, in other words, how does a native speaker 'know' what gender a noun belong to? Models of the mechanisms by which nouns are allotted to genders are called 'assignment systems.' Assignment may involve two sorts of information about the noun: its meaning and its form. We shall consider semantic systems first.

Strict Semantic Assignment Systems

This type is found in Dravidian languages like Kannada, spoken in the state of Karnataka, southern India (Sridhar, 1990, p. 198). Nouns denoting male humans are masculine, those denoting female humans are feminine. There are also deities, demons, and heavenly bodies in these genders. All remaining nouns, including those denoting infants and animals, are neuter. Thus *appa* 'father,' and *candra* 'moon' are masculine, *amma* 'mother' is feminine, and *na:yi* 'dog' is neuter. Certain other Dravidian languages like Kolami have only two genders: nouns denoting male humans are masculine and all others belong in the nonmasculine gender (Emeneau, 1955, p. 73). Elsewhere we also find the reverse. Thus in Diyari, a language of South Australia, there is a gender for nouns with female referents (such as women, girls, doe kangaroos),

and the other is for all remaining nouns (Austin, 1981). In Alamblak, a Sepik Hill language of Papua New Guinea, the masculine gender includes nouns denoting males and those denoting things like crocodiles, pythons, and arrows, which are long and thin, while the feminine is for nouns denoting females or short, squat items like turtles, frogs, and chairs (Bruce, 1984, pp. 96–98; Foley, 1986, pp. 80–81). An interesting system with some similar features is found in Taiap (Kulick and Stroud, 1992).

Predominantly Semantic Assignment Systems

Many languages have semantic assignment rules, which, however, lack the coverage of those seen in Kannada. An example of what we shall call predominantly semantic assignment is found in Tsakhur, which is a member of the Lezgic group of the Nakh-Daghestanian family. Its four genders are shown in **Table 1**.

Assignment to genders I and II is straightforward: I is for male humans (also gods, angels, and so on) while II is for female humans (and female mythical beings). Most remaining animates are assigned to gender III, though a few belong to gender IV, along with some mythical beings. Inanimates are found in genders III and IV (Melínikov and Kurbanov, 1964; Ibragimov, 1999, pp. 54–6; and references therein, Kibrik, 1999, pp. 48–9).

Languages of this general type are widespread. For some of them, researchers have proposed that abstract semantic criteria partly miss the point, and that if we can gain a better grasp of the world view of the speakers, we can then understand the assignment system. The most discussed case is that of Dyirbal, a language of North Queensland (Dixon, 1972), which has four genders, primarily for: male humans and nonhuman animates (I), female humans (II), non-flesh food (III) and the residue (IV). There are numerous apparent exceptions: the moon is in the first, masculine gender and the sun is the second, feminine gender. However, in Dyirbal mythology, as indeed in much of Australia, the moon is the husband of the sun; in Dyirbal the mythological significance of referents is a key factor in assignment. Dixon's data and analysis continue to provoke debate, as shown by the recent paper by Polinsky (1998). There is similar debate as the role of world view in the gender assignment system of Ojibwa (and in other Algonquian language of southern Canada and northern USA).

Table 1 Gender assignment in Tsakhur

Criterion	*Gender*	*Examples*	*Glosses*
male rational	I (masculine)	dak$_j$	father
		gade	boy
female rational	II (feminine)	jed$_j$	mother
		sos	bride
animate (also some inanimates)	III (animate)	balkan	horse
		dadal	cock
		(qow)	(nose)
other (including a few animates)	IV (neuter)	t'et'	flower
		niīse	cheese
		(kabaj)	(butterfly)

In all the languages discussed so far, the meaning of the noun determines gender. In the strict assignment systems, the rules are immediately obvious; in the predominantly semantic systems, there may be a minority of exceptions, but these exceptions have been claimed to be largely apparent in some languages, once the cultural setting of the language is taken into account. If we ask which are the semantic criteria on which semantic systems can be based, we see recurring patterns. Quite often we find animate ~ inanimate, human ~ nonhuman, and male ~ female. Sometimes there is a gender for diminutives, as in various Bantu languages. There are also less usual genders, such as that for nonflesh food (Dyirbal) and the gender for insects (found in the Rikvani dialect of the Nakh-Daghestanian language Andi). A criterion which is sufficient to define a gender in one language may be just one factor in the assignment to a gender in another. Thus the Bantu language Chichewa has a gender for diminutives, while in Dizi, diminutives together with nouns denoting females form a gender.

Formal Assignment Systems

In many languages, assignment by semantic rules would fail to assign many nouns to a gender. While in languages like Kannada the nouns not assigned by the semantic rules (the 'remainder' or 'semantic residue'), all belong to a single gender, in many languages they are spread over more than one gender. In such languages we find additional rules for assigning nouns to genders according to their form. Note the asymmetry: languages may use semantic rules, or semantic *and* formal rules, but not just formal assignment rules. In no language are nouns assigned to genders, as defined earlier, by purely formal rules. An example would be a language in which there were two agreement classes, and the nouns in the first all ended in a consonant cluster, and those in the second did not, and there was no semantic regularity for the distribution of nouns. I claim that this hypothetical type does not exist. Formal assignment rules may appeal to two types of information: phonological and morphological.

Phonological

A clear example of assignment depending on phonological information is provided by Qafar (Afar), an East Cushitic language spoken in north-eastern Ethiopia and in Djibouti (data from Parker and Hayward, 1985). Qafar has rather standard semantic assignment rules, namely that for sex-differentiable nouns, those denoting males are masculine and those denoting females are feminine. It is the nouns which fall outside these rules, the residue, which are of interest. For them the phonological rules apply: nouns whose citation form ends in an accented vowel are feminine (for example, *karmà* 'autumn') while all others are masculine (for example, *gilàl* 'winter,' which does not end in a vowel, and *tàmu* 'taste,' which does end in a vowel, but not an accented one). These rules operate with few exceptions. Moreover, nouns denoting males and females typically fit them too (for example *bàqla* 'husband' and *barrà* 'woman, wife'). It might seem that we could dispense with semantic rules for Qafar, and treat it as being of a quite different type. However, while the phonological rule works for the vast majority of cases, we find the crucial example *abbà* 'father,' which is masculine, even though it ends in an accented

vowel, which 'should' be an indicator of feminine gender. Conversely, *gabbixeèra* 'slender-waisted female' is feminine, though the accent is nonfinal. Qafar is remarkably for the simplicity of its phonological assignment rules, and for the fact that when the semantic and phonological rules are both applicable, they almost always give the same result. However, in cases of conflict, the semantic rules take precedence (as is the normal situation in gender assignment systems).

Other examples can occur in various parts of the world. Even French, often claimed to have no system to its gender assignment, has been demonstrated to have a phonological system, though not as simple as that of Qafar. For example, of 938 nouns ending in $\tilde{\varepsilon}$, 99% are masculine (like *le pain* [p $\tilde{\varepsilon}$] 'the bread'). And of 1,453 nouns in/3/, 94.2% are masculine (like *le ménage* [mena:3] 'the household' (for details see Tucker et al., 1977).

Morphological

In Russian, which is typical of many other Indo-European languages, nouns denoting male humans are masculine and those denoting female humans are feminine. But unlike the situation in languages like Kannada, it is not the case that the semantic residue is assigned to the neuter gender; in Russian the residue is shared between the three genders, with the neuter gender not even receiving the majority. Searching for additional semantic criteria is not at all promising, as the following data suggests (Table 2).

If we look instead at the morphology of the nouns, then we can make progress. There are four main inflectional classes in Russian, each with several thousands of nouns (for justification of this not uncontroversial view see Corbett, 1982, pp. 202–11). There are six cases and two numbers (though no paradigm has 12 distinct forms because of various syncretisms). We give just the singular forms in Table 3.

The native speaker needs to know how a noun inflects, in order to produce grammatical utterances. On the basis of that information, the assignment rules are straightforward. Nouns in class I are masculine, those in classes II and III are feminine, and those in IV are neuter. At first we might think that the semantic assignment rules are superfluous, since *mal'čik* 'boy' is in class I, while *devuška* 'girl' is in class II, and *mat'* 'mother' is in class III. In other words, many of the sex-differentiable nouns would be assigned to the appropriate gender by the morphological assignment rules. But there are also instances where this is not so, for instance, *djadja* 'uncle,' which denotes a male but is in class II, whose nouns are typically feminine. *Djadja* 'uncle' is masculine. Nouns like this show, once again, that we do not find languages where formal assignment rules are sufficient. Further rules are required in Russian for indeclinable nouns (like *taksi* 'taxi,' which is indeclinable and neuter). Morphological assignment systems are found in various other Indo-European languages. Looking further a field, in Arabic too, gender is assignable in the main according to morphology (Cowell, 1964, pp. 372–5).

The different types of assignment criteria may overlap in ways which make it difficult to establish their relative weight in a given language. Thus there may be small clusters of nouns which can be accounted for by semantic criteria (apart from those covered by the main semantic rules) even within systems where formal rules have a major role (as shown for German by Zubin and Köpcke, 1983, Köpcke and Zubin (1996). However, whenever gender languages are analyzed in sufficient detail, the gender of the vast majority of nouns turns out to be predictable.

Table 2 Russian nouns belonging to the semantic residue

Masculine	*Feminine*	*Neuter*
žurnal 'magazine'	gazeta 'newspaper'	pis'mo 'letter'
dom 'house'	izba 'hut'	zdanie 'building'
čaj 'tea'	voda 'water'	pivo 'beer'
dub 'oak'	sosna 'pine'	derevo 'tree'
ogon 'fire'	peč' 'stove'	plamja 'flame'
avtomobil' 'car'	maš ina 'car'	taksi 'taxi'
stul 'chair'	taburetka 'stool'	kreslo 'armchair'
den' 'day'	noč' 'night'	utro 'morning'
čas 'hour'	minuta 'minute'	vremja 'time'
nerv 'nerve'	kost' 'bone'	serdce 'heart'
nos 'nose'	ščeka 'check'	uxo 'ear'
lokot 'elbow'	lodyžka 'ankle'	koleno 'knee'
flag 'flag'	èmblema 'emblem'	znamja 'banner'

Table 3 Inflectional classes in Russian

	I	*II*	*III*	*IV*
NOMINATIVE	žurnal	gazeta	kost'	pis'mo
ACCUSATIVE	žurnal	gazetu	kost'	pis'mo
GENITIVE	žurnala	gazety	kosti	pis'ma
DATIVE	žurnalu	gazete	kosti	pis'mu
INSTRUMENTAL	žurnalom	gazetoj	kost'ju	pis'mom
LOCATIVE	žurnale	gazete	kosti	pis'me
gloss	'magazine'	'newspaper'	'bone'	'letter'

Prospects

Studies on grammatical gender continue to appear regularly, including valuable studies of previously unresearched languages. Here we highlight two main areas where we can expect substantial new developments: lexicology and modeling.

Lexicology

Gender is a key category for lexicology, since it is crucial for understanding the nature of lexical entries. In a gender language the gender of a noun must be available. On the other hand, as we have seen, it does not normally need to be specified, since the information can be derived, by assignment rules, from other information which must be stored. We still do not know the full range of information which may be relevant (for instance, the possible semantic features which may determine gender assignment).

There are further surprises: it is possible too for certain nouns to be of different genders according to the sex of the speaker; this is found in Garifuna, a member of the Arawak family spoken in Belize, Honduras, Nicaragua, and Guatemala (Taylor, 1977, p. 60; Munro, 1998). These two points raise interesting questions as to the shape of lexical entries,

a general question which is of concern to lexicologists and increasingly to psycholinguists (see, for instance, Berkum (1996).

Modeling

When discussing some types of assignment system, the evidence is so clear-cut that alternative analyses are hard to imagine. However, with morphological assignment systems, particularly when the number of genders and the number of inflectional classes is similar in a given language, there are other possible analyses, in particular some would specify gender in the lexical entry and derive inflectional information from it. Arguments in favour of the approach taken in Sect. 3.3.2 include the following; first, and primarily, it is claimed that in languages like Russian the internal evidence shows that the gender from inflectional class approach is preferable (it proves impossible to predict inflectional class from gender but it is possible to predict gender from inflectional class); and second, there is the typological claim that one or other of the possible types of assignment system (or some combination) will always be in play in a gender language such that gender is predictable for the vast majority of nouns and so if the Russian type system were treated differently this would create an anomaly.

However, there is a further step which we can take, of a rather different nature. Since the Russian type languages are crucial, it worth investing additional time in clarifying them. Hence in Fraser and Corbett (1995) we give an account of the Russian gender and inflectional class relations in the Network Morphology framework. The analysis is implemented in the lexical knowledge representation language DATR (Evans and Gazdar (1996, Gazdar forthcoming), which means that the analyses can be verified by computer. Given minimal lexical entries for nouns our account does indeed predict the right genders for a wide range of nouns. An account like this which is both explicit and testable is not available for the alternative approach.

A more complex type is that in which gender is again assigned according to morphological class, but where the morphological class is itself predictable. One such case is Arapesh; a language of the Torricelli family, spoken on the north coast of Papua New Guinea. Genders and morphological classes form a substantial part of Fortune's (1942) grammar, which led to work based on it by Aronoff (1992, 1994, pp. 89–114). Once again, there are semantic assignment rules based on sex. But then there are morphological assignments rules, which determine 13 genders on the basis of 22 morphological classes (which are in turn predictable largely from phonological information). Again we have demonstrated how this system can be analyzed within the Network Morphology framework and have provided an implementation to demonstrate that our claims are indeed valid (Fraser and Corbett (1997). There is a complex interaction of assignment to gender and to morphological class in Mayali, a non-Pama-Nyungan language of north Australia, which has four genders and five morphological classes for nouns. For the essential data see Evans (1997) and for details of a formal model of this system see Evans et al. (2001). Finally, there is interesting work on the development of assignment systems over time, including some modelling: see Comrie and Polinsky (1998), Polinsky and Everbroeck (1998), Polinsky and Jackson (1999).

Conclusion

Gender remains a puzzling category, apparently deeply embedded into the structure of some languages, and missing in other. This is found even in related languages: thus several Indo-Aryan languages have two or three genders, with substantial agreement, while another, Bengali, has no gender even in the personal pronouns. Where we find gender, the assignment rules can be simple, as in Kannada and Qafar, or complex as in French and German. It is an area in which gradual progress is being made and one in which there is still much to learn.

Gendered Care and Social Work Practice

Abstract

This article plots the contribution of feminism to theory and practice in social work. Explorations of practice through a gender lens reveal that essentialist assumptions and stereotypes of male and female characteristics and behavior have underpinned welfare provision and social work practice within it, especially in the area of care work. The article documents how social work has responded to developments in feminist thought especially in relation to how the 'ethic of care' has informed debates about the gendered nature of care in social work.

Introduction

Social work in western society has its roots in the philanthropic movements of the late nineteenth and early twentieth centuries but has developed into a professional activity supported by high-quality education (see Social Work Education) and research. The organization of services may differ between countries, but the rationale for its existence and assumptions about what social work entails are universal. Globally, social work emerged initially as a profession of women dealing mainly with issues pertaining to women's situation. These issues, or domains of social work, involve primarily family and child welfare and the welfare of adults including older people, people with physical disabilities and learning difficulties, and those with mental health problems. The latter categories include both women and men as users of services, but the focus of social work has been on women as sources of support and informal care provision.

In some countries, social work has also had a role in criminal justice systems. The predominance of men in the criminal justice system and expectations about who should work with them has at times led to challenges and assumptions that social work was for women and by women. Also, simple gender analysis which attributed certain characteristics to men and women had implications for the treatment of women in the criminal justice system. A simple gendered analysis that men predominated in the criminal justice system because they were 'naturally' more delinquent and/or violent than women had unhelpful consequences for women (Gelsthorpe, 1989). As Gelsthorpe and others (Heidensohn, 1985) argued, women in the criminal justice system were seen to be doubly deviant: they offended against the law but they also offended against concepts of femininity. Violent women were triply deviant and women who were violent toward their own children were demonized. Analysis of this portrayal and treatment of women in the criminal justice system led to more complex discussions about understandings of gender and gendered social work practice (Orme, 1994).

Social Work and Feminism

Early theorists of social work practice gave little attention to the implications of the dominance of women in the workforce. The welfare system was at best gender unaware or at worst misogynist. For example, there were expectations of a caring profession influenced by feminine characteristics of passivity and maternal instincts. Women dominated in 'caring' professions such as nursing, education, the hospitality industry, and social work. The gendered nature of social work, that is, recognizing certain qualities as female, was first identified by Alice Salomon, a German feminist social work scholar writing at the beginning of the twentieth century who described social work as 'motherly love' (see Kuhlmann, 2008). The positive aspects of such a concept were associated with the responsibility of social workers to provide care and be caring on behalf of the state. But female-dominated professions commanded little respect or influence, despite the invaluable contribution they made to welfare provision (Williams, 1993).

In the United Kingdom, the first observations on the female nature of the workforce was in the Younghusband reports of 1947 and 1951 when it was seen as a deficit of the profession and led to conclusions that efforts should be made to recruit men into the workforce. This was done by professionalizing social work through increased qualifications and salaries. This led, from the 1960s onward, to an increase in men joining the profession. However, the front line workforce remained predominantly female while men who were recruited were quickly promoted to managerial positions (Nottage, 1991). This was in part a result of the very maternal instincts identified as necessary for the professions. Policies were based on expectations that women's careers would be interrupted by childbirth and theories of attachment in child care and development which underpinned social work policy and practice constrained women to be primary full-time carers. Hence, a spiral of gendered assumptions based on notions of caring led to a lack of recognition of women and opportunities for them in the paid workforce and confined them to domestic and caring roles.

It was this conundrum of women in the caring workforce and the challenges from mainstream feminism that precipitated a response from women in social work and focused their attention on issues of gender in the policies, practices, and theories relating to the profession (Hudson, 1985; Dominelli and McLeod, 1989; Dominelli, 1991).

The challenge from feminism focused on women's domination of and their role in the social work workforce. In the 1970s, radical traditions in social sciences of which

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28034-3

second-wave feminism was an important strand began to provide a critique of social work and women working within it (Wilson, 1977). The relationship between gender and welfare was analyzed by social policy feminists (see Orme, 2001; Daly, 2012 for an overview). It was argued that feminists working within welfare may be compromised because they were involved in shoring up state provision that contributed to the continuing oppression of women. The individualized approaches of social work focusing on counseling and casework were associated with a 'band aid approach' (Jagger, 1995) which denied or ignored the need for social change. Women social work practitioners were accused of preserving the status quo.

The engagement of social work theorists within feminism led to a response which initially emphasized women-centered practice. This approach both identified deficiencies in mainstream social work theory in the attention it gave to women and documented the positive contribution that women in general and feminism in particular made to practice (Brook and Davis, 1985; Collins, 1986; Marchant and Wearing, 1986; Hanmer and Statham, 1988; Dominelli and McLeod, 1989). This growing body of work concentrated on both the condition of being a woman and the conditions that women experienced (Orme, 2002a) and led to specific recommendations for intervention identified as feminist social work practice (see Hanmer and Statham, 1988 for a specific code of practice). These included among other things recognizing the conditions of women; always listening to women; raising consciousness of women who were oppressed by their conditions; providing women-only spaces; and identifying commonalities and diversities between women workers and those who used the services.

This codification of practice provided prescriptions for working with women, but it was argued by some (Payne, 2005) that this offered no extensive account of how feminist theory could be applied to generalist social work practice. However, analysis of the impact of feminist theories on social work over time demonstrates that it has had significant influence (Orme, 2012). This influence is not in the form of a particular way of 'doing' social work. The different political strands within feminism are variously described and include liberal, socialist, Marxist, radical, and black. This diversity means that feminism does not provide a single, coherent, and unified way of analyzing and conceptualizing the world. This is a consequence of its exploration of theory but it can be problematic for those practitioners looking for prescriptions for action. Over time, feminist social work theory has engaged with these different positions and now provides a multifaceted approach to social work. This includes particular approaches to practice such as recognizing commonalities and diversities between women workers and service users in one-to-one work (Hanmer and Statham, 1988); narrative approaches (Milner, 2001); community approaches (Dominelli and McLeod, 1989); and group work (Cohen and Mullender, 2003). Developments informed by feminist thinking can be summarized in three main approaches:

- synergies between feminism and social work based on shared values. This involved comparing the mantra 'the personal is political' the social work requirement to deal with the person within their environment (Collins, 1986);
- prescriptions for women-centered practice developed solely from the standpoint of women (Dominelli, 2002) and the implications of this for working with men (Cavanagh and Cree, 1996); and
- use of feminist perspectives to understand the gender dimensions of social work practice that challenge stereotypical assumptions of male and female qualities and behavior (Orme, 2001).

Underpinning these developments was the challenge presented by postmodernist thinking to feminism in general and feminist social work in particular. The prescriptions for action based on women-centered social work were thought to 'essentialize' both women and men according to stereotypical gender definitions. However, while some in social work embraced postmodernism arguing that it reflects feminism's own challenge to overarching male-dominated theories (Fawcett et al., 2000), others suggested that it undermined the political project of both feminism and social work (Dominelli, 2002) or that it was associated with 'academisation' (Gray and Boddy, 2010) which distanced it from practice. Although Gray and Boddy saw the need for acknowledging diversity and difference both between women and men and within the categories 'women' and 'men,' they argue that this was more effectively offered by a different political perspective, postcolonial feminism (2010).

The debates about the different political approaches within feminism and their potential contribution to social work can be illustrated by two significant welfare issues which became the specific focus of feminist social work and help explore understandings of gendered care. These were the response of feminist social work to men who were violent or abusive to women and children and the impact of responsibilities for caring on women's lives.

Gendered Care and Social Work Practice

As has been said, the original gender assumptions in welfare stemmed from beliefs about the essential nature of femininity. Women were expected to be 'the angel in the house' because of their capacity for nurturing which it was said, in a position which echoed Salomon's earlier statements, stemmed from their maternal instincts. These characteristics, assumptions of the 'feminine,' were thought to be necessary for maintaining care services but they were also associated with attributions of passivity which carried negative connotations (Hudson, 1989). It is this paradox that has led to the work on an ethic of care (or alternatively care ethics) becoming influential in understandings of gendered care in social work.

Care Ethics

Over the past two decades, debates involving the deconstruction of dichotomous thinking about men and women have been influential in both theorizing about care in general and the implications of the ethic of care for policy and practice. Originally based in social psychology on the work of

Gilligan (1982), care ethics has become a body of theory that has expanded to inform both theory and practice. Significantly, initially there was surprisingly little attention to the implications of an ethic of care from practitioners in professions that provided care such as nursing and social work. For some, the notions of social work and care were synonymous to the extent that the terms social work and social care were interchangeable, but attention to debates about care ethics within the wider social sciences was largely ignored in social work literature until the early twenty-first century. This may have been because they saw it as an uncontested concept and took for granted an understanding of care because, as is documented earlier, their professions were based on particular constructions of care. Recent work has not only focused on understandings of care ethics in general and their implications for social work practice in particular (Orme, 2001; Parton, 2003) but also debates about notions of justice (Held, 1995; Orme, 2001, 2002b) and identity (Fawcett, 2000; Orme, 2001). This work, as will be discussed later, has unraveled certain complexities.

Gilligan (1982) set out to challenge the work of Kohlberg (1981) whose studies in moral development had concluded that women had inferior moral reasoning to that of men: or more accurately women stayed at an inferior stage of moral development. Initially, Gilligan appeared to reinforce differences based on definitions of male and female in that from her empirical studies she argued that men operated from a logical rational ethic of justice while women operated from a relational ethic of care. It was this ethic of care that constituted women's 'different voice.' Significantly, Gilligan rooted her arguments in object relations theory. This is a branch of psychoanalysis which emphasizes the impact of early childhood experiences on an individual's subsequent interpersonal relationships (see Fairbairn, 1952 as one of many writers on this subject). The experiences focused on were seen as 'objects' but these objects included people, particularly mothers. Gilligan theorized that because mothers experienced their daughters as less separate, these daughters had less experience of separateness and boundaries and were therefore more connected in later relationships. This in turn gave them a greater capacity for empathy and sensitivity toward others. According to Gilligan, this enabled them to operate from an ethic of care. Boys, however, experienced separateness from their mothers at an early age and had to suppress feelings of intimacy and dependency which made them operate from the basis of an ethic of justice. There are, therefore, echoes here of the understandings of feminine caring based on 'maternal' qualities and motherhood that had permeated the profession of social work.

Although Gilligan's work made a major contribution to understandings of care by challenging orthodox thinking about moral development, there appeared to be orthodoxy in her thinking around gendered roles. Hence, there were criticisms of her position (see Featherstone and Morris, 2012). Her distinction between an ethic of care and an ethic of justice was seen by some as unhelpfully essentializing differences between men and women. In defense, Gilligan (1982) argued that the gendered distinctions were not based on biological differences but that the 'different voice' highlighted alternative ways of relating to and providing services for others. What was significant, Gilligan suggested, was that this voice did not represent an inferior form of moral reasoning but should be privileged above, or at least be equated to, the rational technical ethic of justice.

While embracing an ethic of care, Tronto (1993) and others (Sevenhuijsen, 1998, Koggel and Orme, 2013) focus less on the negative, passive elements of care and more on relational and dialogic approaches. They identify a number of reasons for moving beyond an emphasis on object relations and notions of mothering. In the first instance, many involved in care work (both women and men) are not mothers; and, second, those who are mothers do not always demonstrate the enabling nurturing that is associated with an ethic of care. Tronto, therefore, argues that care is not necessarily associated with either male or female behavior but is a species activity that includes everything we do. Care involves the capacity to take the other's needs as the starting point for what must be done. She identifies four phases: caring about; taking care of; caregiving; and care receiving. These phases are based on four ethical elements: attentiveness, responsibility, competence, and responsiveness. Such an analysis is pertinent to social work because social work practice operates at the public/private interface of welfare provision. Also the importance given to context, interdependence, relationships, and responsibilities to concrete others emphasized by such an analysis highlights that an ethic of care is relevant in the political as well as the personal realm (Tronto, 1993). Care ethics is relevant to both interpersonal caring relationships and the institutions responsible for providing them, including those in the political realm.

In terms of the association of feminist analysis and gendered care some argue that Gilligan's ethic of care was not necessarily feminist (Koehn, 1998). In her attempt to identify specifically feminist ethics, Koehn considers an ethic of broad empathy as a development of, or alternative to, an ethic of care. Empathy is a core concept in social work and is one that has presented paradoxes for feminist social workers. While recognizing the objective conditions of those with whom they work, social workers are expected to understand, accept, and respect individual understandings and expressed wishes. Early women-centered practice advocated emphasizing commonalities and differences as a way of understanding women's experience (Hanmer and Statham, 1988) but in doing so recognized that this challenged the expectations of objectivity by overidentifying and/or becoming overemotionally involved with women service users. Koehn's understanding is useful in that it argues that empathy means more than trying to understand the other's feelings but involves engaging with the other by utilizing analytic discernment and attentive reciprocity (achieved by dialogue). It also means going beyond what can usually be understood and accepted, to recognize "tropes and images that might strike us initially as quite radical and even repellent" (Koehn, 1998: p. 58). This is significant in applying care ethics to gendered social work because it requires the acceptance of men and those, women and men, who have gone beyond the experiences of practitioners. For example, gendered practice requires social workers to accept and work with those who

have committed the 'unthinkable' in child abuse (Featherstone and Lancaster, 1997).

The implications for working with some of the most marginalized within 'care' services – men who abuse women – present the greatest challenge to social work practice based on a standpoint or women-centered approach. Social work within the criminal justice system has had a particular remit to work with such men but this has presented certain challenges to the social work value base if they are seen to be beyond 'care.' Social work more frequently works with those who have been the victims of violence, sexual abuse, and other forms of oppression – and many of these are women and female children – and this has meant that gendered social work has been accused of ignoring the needs of the offender and the oppressor. However, the different feminist approaches in social work identified above meant that it is possible to go beyond a standpoint approach (i.e., one that argued the world should be perceived solely from the 'standpoint' of women). This meant that the needs of male perpetrators should also be considered and led to the reinterpretation of an ethic of justice (Orme, 2002b).

It was the wider understanding of an 'ethic of care' and the way it was set in opposition to an ethic of justice that informed thinking about work with male perpetrators of domestic violence and abuse. While early literature on domestic violence focused primarily on the conditions of women, developments in gendered practice required reconsideration of understandings of gender and the implications of this for social work with perpetrators (Orme et al., 2000). Koehn's understandings of empathy does not mean agreeing with abusive behavior, nor does it involve imputing wants and needs to individuals, nor constraining them by assumptions based on gender stereotypes, but, rather, being prepared to hear the conflicts and confusions. This leads to understandings of an ethic of care that challenge the process of dichotomizing care and justice. Care becomes the mercy that tempers justice (Jagger, 1995). Hence, an ethic of care that incorporates the principles identified by Tronto (1993) and based on a strong conception of rights leads to a caring justice. The obverse of this is that gendered practice also requires 'just care' (Orme, 2002b). Such a concept develops from the critique of 'traditional' caring that has come from women with disabilities and men who care.

As has been outlined earlier, early feminist critiques of care policy focused on the burden of care that fell on women in society (Dalley, 1988). This negative representation of those requiring care was challenged by women who required care. The categorizing of those requiring care into groups defined by their need or their condition (e.g., disabled, old, or mentally ill) denied everyone their personhood, and in particular denied women their womanhood (Orme, 2001). Feminists within the disability movement argued strongly against such categorization pointing out not only that they were women too, but also that they might be providers of care for others (Morris, 1992). Hence questions of identity were being challenged by those involved in the care system.

Universal assumptions of care as burden also challenged the nature of care offered. That care associated with maternal instinct was seen to be positive, denied the potential negative consequences of such care. Mothering can be overbearing and deny personhood often infantilizing those who require care. Rather than reflecting altruism, the provision of care can involve surveillance and the disciplining of those being cared for. Such negative conceptions of care also have expectations of passivity and gratitude on the part of the person receiving it. All of which denies them personhood. Hence, the stages of care outlined by Tronto (1993) have not only liberated those expected to provide care but also those who require care.

An ethic of care based on the processes of care rather than on who provides it has enabled gendered practice to respond to the challenge that came from men who provided care. While early statistics showed women as carers, further analysis led to suggestions that men might be the 'hidden' carers. When evidence emerged that men did provide care, a gendered perspective based on care as a feminine quality suggested that the nature of care provided differed between men and women. It was argued that men provided predominantly spouse care or care in close personal relationships; they did not care for members of the wider family or for strangers (Arber and Ginn, 1990). Men provided care for those they cared about (Rose and Bruce, 1995). This caring 'about' also informed the hypothesis that the nature of the care provided differed between women and men: women provided intimate personal care while men looked after those requiring care, they 'managed' the care rather than providing hands-on care. Also with the involvement of gay men in the buddy system that required intimate caregiving for those suffering from AIDS, the gendered assumptions based on stereotypical male and female characteristics and qualities were challenged (Orme, 2001). Again, Tronto's (1993) phases of care (caring about; taking care of; caregiving; and care receiving) based on the quality of care derived from the four ethical elements (attentiveness, responsibility, competence, and responsiveness) rather than who provides the care have led to changed understandings of gendered care.

A final postscript to these developments is provided by considering the implications of care ethics for the organization of care within the changing nature of welfare. Care ethics is relevant to both interpersonal caring relationships and the institutions based on these including those in the political realm. Developing theories about the application of an ethic of care to policy development and political organization offer a critique of neoliberalism and associated policies (Barnes, 2012; Featherstone and Morris, 2012). This is crucial for social work practice which, even when operating outside statutory organizations, is influenced by political changes. In the United Kingdom, policy development over the last 20 years has become increasingly based on individual responsibility and the marketization of welfare including principles of personalization (Dominelli, 2004).

As was said at the outset, the availability of women as carers was crucial in the development of welfare in the latter part of the twentieth century. Since then in western societies generally, and in the United Kingdom in particular, emphasis on care in the community has meant the closure of institutions and the need for resources for caring to be available in communities. These policies involved care by communities: they moved responsibility for care to individuals, families, communities, and private- and third-sector organizations rather than the state. Later developments involved the creation of 'markets' in welfare

which have involved the commodification of care. Care is no longer based on either altruism or empathy but is something to be purchased. In the first instance, this involved private companies contracted by statutory organizations to provide care previously provided directly by the state (Ungerson, 2003). Most recently, a more individualistic culture developed. Policies which were said to be related to user empowerment led to a personalization agenda where the state rather than provide services allots personal budgets to individuals requiring care, making them responsible for securing and managing their own care. They purchase the services of other individuals. As Barnes (2012) argues, such policies emerge from different but intertwining ideologies. The first is the primacy of the rational, autonomous, self-sufficient individual which can be defined by an ethic of justice and the second is the right of those who are in receipt of services to be empowered, to be involved in the service delivery required to meet their needs which is a manifestation of just caring.

Such developments have implications for understandings of gendered practice. The creation of a 'care market' associated with the commodification of care leads to a set of paradoxes (Orme, 2003). Payment for care, especially in times of economic depression, means that such employment may become attractive to men. While the finances mean that wages will be low, being able to purchase care by male carers might offer more choice to those who require it. Payment for care challenges assumptions that it is the expression of a maternal instinct or an act of altruism associated with 'feminine' behavior. Hence, the myth of feminine care is exploded and opportunities are created for men to behave differently, to operate with, as Gilligan (1982) argued, a different voice. However, such policies also raise questions about the nature of services that are paid for; if it is not motivated by altruism or empathy does providing service constitute care? Having said that when there are insufficient resources either to pay for the level of care required by the individual or to provide the appropriate level of staffing required to meet all the care needs of a personalization agenda, or when the person requiring care is not competent to manage budgets, then the provision of care will again fall disproportionately on women. This is because, despite developments in theory, practice, and policy, public attitudes still perceive care as gendered and that the gender of the carer is feminine.

Conclusion

This article has attempted to demonstrate that gender is integral to social work practice in a number of ways but that understandings of gendered practice have changed over time. Social workers initially argued that social work theory was gender-neutral, feminism challenged this. However, initial attempts to define the gendered nature of the profession led to paradoxes. When a wider and more flexible lens of gender was adopted, this led to a more nuanced analysis of social work practice. First, it highlighted that women-centered practice did not necessarily uphold the values of social work and feminism in its attitudes to working with men. Second, it complexified the role of men in the care workforce. Reworking social work concepts such as individualization by drawing on notions of identity led to an approach to social work that was more inclusive, just, and caring. This drew initially on Gilligan's (1982) theory of an ethic of care but incorporated later developments in moral philosophy which widened the implications beyond individualized social work interventions to the organization of the provision of services.

Gendered care, therefore, constantly challenges how the underlying philosophies and ideologies of policy influence the conditions in which social work can practice. At one level, policy which appears to democratize care, to move it from the power of the professionals and involve those who require it, might be seen to reflect a 'caring' approach. However, if such caring is not based on a true dialogic approach which informs all relationships and interventions from the highly political to the intensely personal, then it is not gendered care informed by an ethic of care because in the words of the feminist mantra the 'personal is political.'

Genealogy in Anthropology

Abstract

More than a century after W.H.R. Rivers formalized the genealogical method of anthropological inquiry, anthropologists are still debating the assumptions written into it through the notion of pedigree, considering the impact of genealogical thinking beyond kinship, and exploring new ethnographic cases. The historical and cultural specificity of Rivers' method percolated into colonial practice. New reproductive technologies used for humans and animals draw upon genealogical thinking in unexpected ways. Record linkage for commercial biotechnological purposes triggered controversy in Iceland and new forms of digital genealogy. New ways of examining genealogy use multidisciplinary approaches explored in three-dimensional exhibition space.

Introduction

More than a century after W.H.R. Rivers formalized genealogy as a method in anthropology, anthropologists are debating the premises of the genealogical model while exploring its historical and contemporary manifestations. (Others caution the emphasis on genealogy at the expense of addressing the unfinished business of kinship terminology (see, for example, Read, 2007).) Some have argued the case for developing alternative ways of theorizing relatedness (e.g., Carsten, 1997, 2000; Ingold, 2000; Franklin and McKinnon, 2001). Others defend the continuing relevance of genealogical thinking for understanding the human condition (Zerubavel, 2012); and the on-going pertinence of the distinction between biological and the social relatedness written into the genealogical framework for understanding kinship (e.g., Astuti, 2009) Historical and ethnographic studies covering a wide spectrum of subjects – from state and colonial uses of genealogy to the intertwining of human and animal pedigrees through breeding ideologies, practices, and stories, to everyday relations intercepted by new reproductive technologies, to popular and digital genealogy – extend, in often unexpected ways, the range and depth of this cultural phenomenon (see Henare, 2007; Bamford and Leach, 2009; Cannell, 2011). On the one hand, the peculiarity of genealogy as a history of relatedness among persons involving the transfer of bodily substance and cultural knowledge that is somehow abstracted from their relationships with the environment has been clearly analyzed (Ingold, 2000). On the other hand, the re-surfacing of genealogical thinking in unexpected places has given a new impetus to empirical research and pushed the study beyond kinship as originally understood (Bamford and Leach, 2009). Anthropologists investigate the way human and non-human pedigrees are interconnected (Cassidy, 2002, 2009). They study the remaking of genealogy whereby the lives of animals, such as sheep, are bound together with humans through old and new technologies of reproduction (Franklin, 2007); and they acknowledge genealogy as a practice shaping and informing everyday life where relations have been forged through the new reproductive technologies (Edwards, 2000, 2009). They have looked at the effects of extending the logic of pedigree and recording genealogies to work undertaken by amateur ethnographers in the early twentieth-century colonial service (Holmes, 2009). They have investigated how the mapping of the human genome has prompted new sets of linkages (in the case of Iceland) between medical records, DNA records, and genealogical records and at the link between pedigree and capital in digital genealogies (Pálsson, 2009; Cunningham, 2009). They delve into the significant contemporary role of genealogy, such as Maori *whakapapa*, whereby a person is the living face of their ancestors and the interweaving of Maori concepts with legal discourse (Henare, 2007). And they examine state suppression of genealogies elsewhere – as, for example, by the Mongolian authorities in the 1930s, which resulted in the destruction, concealment or mutation of Buryat genealogies into other forms – such as photomontages (Empson, 2007), or in the imaginative forms of *bilum* trees (Herle et al., 2009). In arguing against the overpowering effect of the genealogical framework, others have emphasized different geometries – horizontal relatedness and diagonal links – as well as the significance of sustenance, land, memory, and knowledge in constructing relatedness.

The following sections will consider the definition, method, and assumptions of genealogy, bringing in some of the new ethnographic cases of genealogical thinking and imagination and some of the ongoing debates that have taken place.

Genealogy defined

> Genealogy, *n* 1 an account of the descent of a person, family, or group from an ancestor or from older forms; 2 the descent of a person, family, or group from an ancestor or from older forms; pedigree, lineage; 3 the study of family pedigrees. (*Longman Dictionary of the English Language*, 1984: p. 611)

This definition of the term genealogy involves three components: first, it is a *representation* of the descent, which may be written (for example, the Book of Genesis), or graphic (for example, the Tree of Jesse). Second, there is descent as "…the *fact* or *process* of derivation from an ancestral stock, lineage; … transmission or devolution of an estate by inheritance, usu in the descending line … a transmission from a usu earlier source that has had a shaping or developing effect; a derivation-…"(*Longman*, 1984: p. 394). Third, the definition refers to the *study* of family pedigrees: the activities of amateur genealogists

and local historians avidly using censuses and parish records to create new accounts of descent.

The several component layers of genealogy – as an 'account,' as a 'fact or process,' and as a 'study' – hold complex implications for anthropology. The written or graphic account introduces a bureaucratic dimension whereby knowledge, in the form of record-keeping, opens up the potential for manipulation and the exercise of power. The exclusion of those deemed illegitimate is as compelling a dynamic of genealogy as is the cultivation of those seen as rightfully composing the ancestral line. The account is supposed to deal with descent: the links of between parent and child repeated over the generations – backward and forward – with social emphasis placed on the whole series of such links, which vary (see Parkin, 1997). Generational links imply the transmission of 'something' that is shared by descendents and this has been the focus of anthropological study. While some distinguish between genealogy and category (Parkin, 1997: pp. 50–51), others connect the two, arguing that the metaphor of transmission implies that both genetic information and cultural classification are being passed across the generations (Ingold, 2009: p. 196). This re-convergence of the biological and the social, which had been separated in twentieth-century kinship theory, subtends much of the renewal of theoretical interest in genealogy. The study of pedigree dynamics and uses, whether human or animal, or connecting the two, for example in biotechnology, has generated new questions that have given rise to a renewal of interest in genealogy as a field of empirical inquiry in anthropology.

The Genealogical Method

These developments require some historical contextualization. The genealogical method of anthropological inquiry was developed by W.H.R. Rivers during the 1898 Cambridge Torres Strait Expedition, and formalized in articles published in 1900, 1910, making its entry to *Notes and Queries in Anthropology*, in 1912, and subsequent editions. It could be argued that Rivers was building upon an insight by Charles Darwin in *The Origin of Species* (1859). In his natural system of genealogical arrangements, Darwin removed "the connotations of rank and status attached to the fact of knowing one's pedigree" replacing it with "the assumption that *a genealogy is a recorder of natural relations*" (Strathern, 1992: p. 91). Crucially, Rivers's reconfiguration of pedigree into the genealogical method re-focused on human relations, seeking to establish the limits of people's knowledge of kin, by birth and by marriage; and from there, recording their ways of referring to and addressing the persons they had identified. The nineteenth-century intellectual context of this method lay in a rich combination of biblical, philological, heraldic, and evolutionary ideas. Darwinian theories concerning the origin of species and descent of man had recourse to both narrative and graphic genealogical imagery (Beer, 1983; Strathern, 1992). The familiarity of biblical and historical family trees made genealogy a ready vehicle for translating new ideas about the relationships between all forms of life, and the slow transformation (or evolution) of these forms through the immense abysses of geological time that opened up in the nineteenth century. Graphic phylogenies, such as those drawn by Ernst Haeckel (1874), expressed these evolutionary connections in the form of a tree (Bouquet, 1995, 1996).

Genealogies are central to the creation story in Genesis, which was a source of inspiration for late eighteenth- and early nineteenth-century philologists and ethnologists who sought to explain the relationships between the languages (and hence peoples) of the world in genealogical terms. Still earlier, culturally diverse objects brought to Europe from the New World starting in the sixteenth century, were accommodated by Renaissance collections using medieval categories which included 'paganism.' "'Paganism' both allowed the admittance of cultural diversity and provided it with a biblical pedigree," as Anthony Shelton (1994: p. 201) puts it. "The date and circumstances of the divergence of the pagan races from the Christian world in the remote past greatly occupied the minds of the chroniclers who endlessly hypothesized on the origins of the Aztec and the Inca, who they usually related to an obscure offspring of Noah or a lost tribe of Israel … Small wonder, then, that racial genealogies and conjectural histories partly informed written compendiums of customs and arrangements of material culture" (Shelton, 1994: p. 203).

Philological, biblical, and Darwinian genealogical ideas influenced L. H. Morgan, author of *Systems of Consanguinity and Affinity of the Human Family* (1871), in his kinship and beaver research among the Objibwa around Marquette, which took place against a background of wilderness receding from American farms (Feeley-Harnik, 1999). This was rather different from Darwin's invocation of genealogical imagery in his theory of evolution, which was filtered through the ideas of British animal breeders for whom keeping records was an important means of exercising control over procreation. The fact that the British aristocracy could trace their genealogies, just as they could trace the pedigrees of their favorite animals, such as thoroughbred horses, helped to distinguish them in terms of descent and breeding from other ranks. Written pedigrees of thoroughbred racehorses, recorded in the *General Stud Book* (established in 1791), transform knowledge about people and horses in very specific ways (Cassidy, 2009, 2002, and below).

Rivers' genealogical method became a means of organizing fieldwork and written ethnography, despite being later overshadowed by, for example, participant observation (see Malinowski, 1922). The historical incorporation of pedigree into anthropological methodology is a remarkable maneuver in terms of class and cultural capital in the context of early twentieth-century Cambridge (where Rivers was based), which was still then dominated by a few great families. Borrowing pedigree was an assertion of being above this sort of hereditary ranking system, while harnessing its power as a form of intellectual capital for deployment in the comparative study of mankind (see Bouquet, 1993).

Recent research on Kenya shows that genealogical thinking percolated into British colonial administration in early twentieth-century in East Africa. Amateur ethnographers in the colonial service attempted to make sense of the 'turbulent collection of tribes' by privileging descent through men as the source of indigenous identity. "[F]luid and shifting social spaces of indigenous communities were materially reordered as colonial agents established, or invented, the rigid and internally coherent structure of 'the tribe' as the conceptual framework for colonial administration and control" (Holmes, 2009: p. 57).

Given the importance of pedigree in British society generally at that time, Teresa Holmes argues that the link between pedigree and the recording of genealogy can be extended to the activities of amateur ethnographers in the colonial service. Tribal representatives identified through this recorded descent information were seen as providing a natural connection to land 'passed on in the blood from original ancestral settlers' (Holmes, 2009: p. 63). These ideas were particularly problematic in the Nzoia region of Kavirondo, in western Kenya, where Luo had intermarried with Bantu and shared resources. The area was characterized by much movement between communities and disputes over land and trade. Bantu Wanga were identified by the British as primary occupants of the land by means of a map and a genealogy supporting Wanga connections with the land. By 1916, Kager Luo were contesting this interpretation by claiming landowner status for themselves and inviting 'tenants' to support their claims. Holmes' Kenyan research demonstrates how the genealogical model informed both the anthropological paradigm of segmentary lineage systems and the colonial model of the tribe.

Rivers' genealogical method would have been a welcome development not only for anthropologists but also for colonial administrators. It maps informants' knowledge of their relatives by proceeding from the concrete level of personal names to the abstract system of relationships. Rivers explains the steps by which he collected a pedigree (he uses the terms pedigree and genealogy interchangeably.) First, the descendents of the informants' 'real' (as opposed to classificatory) parents were listed, including previous or other marriages, and children listed in order of age, together with their marriages and offspring. The mother's and father's respective pedigrees were collected by following the same procedure. Rivers claimed that the most extensive pedigrees could be collected using only five terms of relationship: 'father, 'mother,' 'child,' 'husband,' and 'wife.' The fact that Rivers treated other categories – 'brother,' 'sister,' 'cousin,' 'uncle,' and 'aunt' – as problematic gave the entire method a lineal bias. Later scholars have argued that lineal relationships were seen as less ambiguous than either collateral or affinal ones (Barnard and Good, 1984). Information concerning social condition, residence, totemic, and other group affiliation, along with other relevant facts, were to be recorded for each person on the pedigree as far as possible. An extraordinarily wide range of topics could be studied in this way. At the heart of the method was the assumption that kinship was about the social recognition of certain genealogical relationships; and genealogy was assumed to be about biology.

Genealogical Thinking

Despite Bronislaw Malinowski's (1930) criticism that genealogy led to the overabstraction of kinship studies and the emphasis he placed on long-term participant observation, the genealogical method proved to have remarkable staying power in the fieldwork toolkit. It became one of the principal methods of ethnographic fieldwork during subsequent decades providing material for structural-functionalist analyses and theories of social organization. Although the study of kinship had faded from the forefront of discussion by mid-century, collecting genealogies remained part of the ethnographer's stock-in-trade, and genealogical diagrams became one of the minimum requirements for making fieldwork intelligible (Barnes, 1967). Genealogy began to be critically scrutinized from the late 1960s when David Schneider published his cultural account of American kinship (Schneider, 1968): there were calls for a social history of the genealogical tool (Bourdieu, 1977), and anthropological assumptions about the 'genealogical unity of mankind' underlying kinship studies were called into question (Schneider, 1984).

A number of critical studies and ethnographies of kinship, during the 1990s, helped to reinvigorate the study of genealogy as a matter of theoretical interest and ethnographic interest (e.g., Strathern, 1992; Bouquet, 1993; Carsten, 1997; Franklin, 1997). Since 2000, ethnographic research and theoretical debate concerning genealogy have taken several distinctive directions: there is a strong – though certainly not exclusive – focus on Britain. This trend, seen in Holmes' work discussed above, is also exemplified by Rebecca Cassidy's work on thoroughbred horse breeding (Cassidy, 2002, 2009), and Sarah Franklin's research on sheep breeding (Franklin, 2007). Cassidy found that since, among horses, breeding sells, pedigree must be regulated. Among racing enthusiasts, breeding suggests entitlement. Cassidy found the grammar of pedigree compelling "for people who act on the principle that 'like begets like'"(Cassidy, 2009: p. 26). In fact, she found that pedigrees run through all the stories the racing world tells about itself. The conflation of human and animal is used to express the logic of pedigree, including the idea of improvement as a means of increasing status; and the exclusion of nonracing family members and prevalence of patriarchy.

The intertwining of human and animal genealogies in the racing world recurs in the shared genealogies of humans and sheep (Franklin, 2007). Sarah Franklin draws upon 'the very conservative idiom of genealogy' to understand the sheep Dolly as a genetic mix – the merging of two cells through a technique of 'decapacitation' (Franklin, 2007: p. 41). The analysis stretches back into the past of sheep domestication, the role of sheep in the colonization of Australia, and forward through new breeds such as Dolly, to try to make sense of the life and death of this particular animal. Franklin delineates a "method of genealogical reckoning that not only looks back at how certain conditions came into existence but at how they are orientated toward the future, and how they can be seen as promissory repositories of the future" (Franklin, 2007: p. 127). The case of Dolly thus provides a window on the remaking of genealogy: the human–animal relations that emerge from new reproductive technologies, but which belong to a descent pattern already known from agricultural experimentation in pursuit of new commercial markets (Franklin, 2007: p. 155).

Genealogical thinking and breeding practices criss-cross the human–animal boundary, calling into question the notion of a genealogical unity of mankind.

Digital Genealogy

Information technologies play a major role in the new commercial, biomedical, and cultural uses of genealogy. The connection between biomedical research, genealogical records, health records, and state sanctioned commercial record linkage

in Iceland generated controversy and attracted the attention of theorists to online genealogy (Pálsson, 2009; Cunningham, 2009). Iceland's relatively homogeneous gene pool, combined with excellent medical and genealogical records (reflecting the Icelandic cultural passion for genealogy), made it eminently suitable for commercial research to identify the genetic codes responsible for common diseases and the development of drugs for their treatment. However, record linkage and the creation of commercially financed centralized databases – the Book of Icelanders and the Health Service Database – by the (American venture capital financed) company deCODE together with Frisk Software led to controversy about the role attributed to private companies by state legislation. The companies were challenged in the courts by publishing company Genealogia Icelandorum on the grounds of violation of property rights (Pálsson, 2009: p. 99). DeCODE's response was that 'genealogical records are the common heritage of all Icelanders' – a tradition they proposed to perpetuate by making genealogical records accessible to the public online (Cunningham, 2009: p. 131). Accessing the highly visible web version of the Book of Icelanders database became a popular pastime among Icelanders. However, it also had unforeseen consequences as unknown relations were exposed, or people were omitted; it created anxieties about citizenship, personhood, and property rights, as genealogies were removed from the sphere of social history and relocated in the sphere of biological commerce (Cunningham, 2009: p. 134). Although the capitalization of human genes involves reconfiguration of traditional alignments between heredity, family, and character, this reorientation always takes place in geopolitical, economic, social, and cultural contexts such as Iceland. One significant finding was that not only new, horizontal connections are important but that old ideas about the vertical movements of genes, orchestrated by consumer choice and directed genetic mobilities, also remain important in the era of genomic technologies (*idem*).

Diagonal Genealogy

The question of how the genealogical model might be mobilized to narrate connections forged through novel forms of conception is posed by Jeanette Edwards in reflecting on her research into the new reproductive technologies in Alltown (Edwards, 2009). Edwards questions whether all English folk draw on genealogy in the same ways and, if they do, whether genealogical links are as fixed and uncompromising as the model might suggest (Edwards, 2009: p. 138). Of course, the early twentieth-century middle-class English folk model of pedigree that Rivers formalized into the genealogical model was both historically and class-specific. As Holmes' work shows, its extension into administrative procedures by amateur ethnographers in the colonial service coincided historically with Rivers' formalization of the genealogical method. So the ethnographic question Edwards raises is also a historical one. It concerns the specificities of cultural capital formation and deployment among historically specific classes and class fractions as that exemplified in the genealogical method. If genealogy was further democratized over the course of the twentieth century, through digital genealogy, through the availability of new reproductive technologies, and through commercialization, then it is rightly called an ethnographic question.

Hilary Cunningham's discussion of Icelandic genealogy identified both horizontal and vertical movements arising from commercialization and popular understanding of gene mobility. The 'diagonal' genealogical links identified by an Alltown youth and community worker, when discussing sperm donation between fathers and sons, echoes these new geometries of kinship. Edwards' interest in what she terms the less pure side of the genealogical model, prompts her to examine the limits of the model, and the 'trickiness' with which actual and lived relationships cut across it (Edwards, 2009: p. 139).

'Young mums,' meeting weekly at a community center, commenting on the newspaper reports of widespread sperm donation by fathers to their sons, rejected as repugnant the scenario this conjured up for them – of sexual intimacy with their boyfriend's father, physical incorporation of his sperm, and the confusion of kinship roles (Edwards, 2009: p. 142). In a conversation with an older woman, the thinking through of complexity went a step further: what about boyfriend's mother's involvement in the negotiation? And what about the legal and emotional implications of being simultaneously father and grandfather? The confusion of generational roles and temptation to intervene in child rearing were seen as substantial obstacles to proper family relations. Problems were anticipated for the man who wanted to continue to help after the child's birth due to their double relationship, which would compound existing tensions between parents and grandparents over child raising.

While Edwards focuses on the way genealogy informs and is informed by relations forged through the new reproductive technologies, Fenella Cannell examines the uses of popular genealogy in remaking kinship relations with the dead (Cannell, 2011). Cannell emphasizes the social dimension of English amateur genealogists work, contrasting it both with the 'narcissistic' Parisian genealogists portrayed by Martine Segalen and Claude Michelat (2002) as being engaged in a compensatory activity and with American kinship, where the dead do not count as kin. Amateur genealogists in East Anglia, by contrast, invest considerable effort in researching their dead as part of a process of recuperation: knowledge allows the deceased to become actual rather than potential family members. While media dramatization of celebrity family histories – such as Jeremy Paxton's – gained mainstream viewing time, Cannell emphasizes the richness of off-screen genealogy: visiting houses, long rolls of paper trees, albums and boxes of photos, pamphlets about local history, and many stories – all of which create a space for restitution (Cannell, 2011: pp. 469–470). Although genealogical talk often seems to revolve around the self, Cannell does not see this as an 'attenuation accompanying modernity,' but rather a construction of the self through past others (Cannell, 2011: p. 473). She sees the access to databases and the Internet during the 1990s as expanding an existing interest. East Anglian genealogists can be seen as part of a democratizing trend, and a long tradition of asserting that history is not a possession of the privileged. Contrary to the idea of ancestral pedigree, popular genealogy, after World War I, can be seen as part of the shift toward democratic commemoration.

The underlying questions of morality to which both Edwards' diagonal genealogies and Cannell's popular ones refer,

demonstrate that genealogical thinking is more flexible and adaptable than was thought at the end of the twentieth century. One of the reasons why anthropologists have been so critical of the genealogical model as it has been used in anthropology is because its assumptions obscure the life worlds of the very people anthropologists claim to understand (see for example, Viveiros de Castro, 2009). Tim Ingold argues that the genealogical model profoundly misrepresents the way people we (anthropologists) class as indigenous "actually constitute their identity knowledgeability, and the environment in which they live" (Ingold, 2000: p. 133). In this, the genealogical model is deeply implicated in the discourse of the state; indeed, it is 'fundamentally a colonial model' (Ingold, 2000: p. 151). But what are the assumptions of the genealogical model to which Ingold refers?

Genealogical Assumptions

David Schneider was the first to draw attention to the assumptions underlying American kinship, which distinguishes between nature (blood) and law (marriage) (Schneider, 1968). His point was that this assumption colored anthropologists' understandings of kinship: taking for granted the facts of sexual reproduction and classifying relatives from there profoundly shaped the way non-western people's kinship and lives have been studied. An assumption about the genealogical unity of mankind was central to this process (Schneider, 1984). Early twentieth-century formalization of the genealogical method exemplifies how this perspective became embedded in anthropological method (Bouquet, 1993, 1995, 1996).

Ingold (2000: p. 136) points to the peculiarity of linear genealogy as a form that unfolds without regard to people's relationships due to the assumption that "original ancestry lies at the point where history rises from an ahistorical substrate of 'nature'; that the generation of persons involves the transmission of biogenetic substance prior to their life in the world; that ancestral experience can be passed on as the stuff of cultural memory, enshrined in language and tradition; and that the land is merely a surface to be occupied, serving to support its inhabitants rather than to bring them into being" (Ingold, 2000: p. 133).

Returning to the way Rivers' genealogical diagram 'upends' the potent image of the family tree (*cf* Bouquet, 1995, 1996), Ingold argues that the effect of this inversion is to replace the tree as a living, growing entity with "an abstract dendritic geometry of points and lines" (Ingold, 2000: p. 135). He asks, "What, exactly, is implied by this line? … [W]hat does it leave out?" (idem).

An assumption at the core of the genealogical model is that "individuals are specified in their essential genetic and cultural constitution – as genotype and culture type – in advance of their life in the world, through the bestowal of attributes from ancestors" (Ingold, 2009: p. 196). Since this transmission takes place at a remove from the surrounding environment, the genealogical model implies the transmission of 'vertically integrated classificatory knowledge.' Ingold proposes the reverse is also true: "the project of classification, combined with a principle of transmission by descent, generates the genealogical model" (*idem*).

Sandra Bamford and James Leach (2009: p. 2) argue that ideas about sequence, essence, and transmission behind the genealogical model "structure other modes of practice and knowledge making in domains that lie well beyond what we normally label 'kinship': … race, personhood, ethnicity, property relations, and the relationship between human beings and nonhuman species" (Bamford and Leach, 2009: p. 2). What does this mean for the genealogical method? Not all would agree with the harshly critical line taken on the comparative value of the genealogical method. Rita Astuti imagines W.H.R. Rivers enquiring into real versus classificatory kin among the Vezo of Madagascar (Astuti, 2009). She argues that much can be learned from the fact that people can make this distinction but are reluctant to do so. The Vezo ignore distinctions that are central to the method (such as parent–child bonds being distinct from all others), and their cultural practices obscure the pedigrees that the method is supposed to reveal – such as finding resemblances between parents and children (Astuti, 2009: p. 220). Astuti argues that there are two ways of interpreting these findings: either by asserting that Vezo ontology does not reveal a distinction between the 'facts of biology' and the 'facts of sociality,' and declaring Rivers' method inadequate; or by questioning whether Vezo cultural practice can be seen as reliable evidence of their 'ontological commitments.' The problem, as Astuti succinctly puts it, is that the method fails to capture the efforts through which these distinctions are made irrelevant (*idem*).

Vezo consciously play down the ties of biological kinship, to obscure pedigrees and to reduce the distinction between birth and nurture so as to build a community where children are 'generated, nurtured and moulded' through a wider circle of relations than the 'facts of biology' would admit (Astuti, 2009: p. 229). One of the unintended consequences of the genealogical method and its assumptions may thus be to reveal difference and complexity in a positive rather than a negative sense. These qualifications help to explain why anthropologists have continuing recourse to genealogy, despite – perhaps because of – the critical deconstruction of both method and model.

The Genealogical Imagination

What effect does the representational process of genealogy have upon the perceived rigidness or flexibility attributed to the model? As Cannell observed, "genealogy is a process by which the dead are brought back to some form of social life, the life of kinship, through the work and journeys (both literal and emotional) which the living descendants undertake on their behalf" (Cannell, 2011: p. 469). But what about people who keep, or kept, genealogies in other parts of the world? The close association between genealogy and the state, to which Ingold pointed, had implications for the Buryats, who migrated from Russian Buryatia to Mongolia in the early 1900s, and who were persecuted during the 1930s early Socialist period (Empson, 2007). During mass purges, almost all male Buryat were taken away, leading their survivors to conceal evidence of kin reckoning and personhood. Genealogical diagrams going back seven or eight generations were burned or concealed at the bottom of chests – along with Buddhist icons and shamanic implements (Empson, 2007: p. 119).

Rebecca Empson, in her analysis of the Buryat household chest, describes how photomontages came to replace

genealogies, which were displayed on each side or above the central mirror, as a means of representing kin (Empson, 2007: p. 120). She observes that unlike kin diagrams, Buryat genealogical representations start from a cluster of male descendants, expanding outward from a single founder in the middle or at the top of the page. The photographic montages mirror some of the compositional forms used to represent relations in traditional Buryat genealogies: a photograph of the patrilineal elder, with his wife, is placed at the center of the frame, surrounded by siblings and children, extending out to the frame. However there are significant differences: those linked in the photographic displays include both mother's and father's sides, school friends, people from summer pastures, colleagues from work, and people at other social events. Furthermore, the piling of photographs, with new ones constantly being added, means that the old ones at the back become obscured. 'Photographic montages thus replicate Buryat genealogical diagrams in their form, but extend their content to include other types of relations' (*idem*). These visible, infinite relations contrast with things hidden inside the chest (umbilical cords, locks of hair), which constitute a site for the subterranean relations between those of 'shared blood' – too close to live together but intimately connected by 'blood feelings.'

The exhibition 'Assembling Bodies: Art, Science and Imagination' at the Museum of Archaeology and Anthropology in Cambridge, 2009–10, staged a Mongolian Buryat chest based on Empson's research. Also on display was a *Bilum* Tree installation, designed by Marilyn Strathern, comprising netbags collected in Papua New Guinea between 1922 and 2005, strung plumply around a pole. Both installations powerfully materialized different ways in which genealogy is being re-thought, as well as the value of thinking through the things that go to make relations – and re-shape them (see Herle et al., 2009; Geismar, 2009).

By moving beyond the two-dimensional abstractions of written and diagrammatic genealogy into the complex three-dimensional ways genealogy is being materialized and transformed, in contemporary art as well as by science, this way of thinking and modeling the world is being put in its place. This place includes the three-dimensional space of exhibition and the assembly of materials there: as a space of modeling, experimentation, and reflection.

Abstract

Gene-culture coevolution theory explicitly accounts for the inheritance of genetic and cultural traits whose fitness and evolutionary trajectory are nonindependent. After describing how a gene-culture coevolutionary account is constructed, the framework is compared and contrasted against other evolutionary anthropology approaches to the study of human behavior. This is followed by highlighting a series of examples of gene-culture coevolution in human evolution, focusing largely on nutrition, disease, and the role of cumulative cultural evolution, which also shows how gene-culture coevolutionary mechanisms can affect both rates and evolutionary trajectories compared with a standard population genetic or cultural account. The approach is a powerful tool to understand both ancestral and contemporary human evolution.

Introduction

Coevolution refers to a form of evolution in which heritable traits affect each other's fitness. Within biology, famous cases include the antagonistic coevolution in either predator-prey or parasite-host systems, where an arms race can ensue as adaptations for predation or infection coevolve with countermeasures in the prey or host species. Most of these coevolutionary systems require evolution purely through genetic inheritance. By contrast, gene-culture coevolution concerns the evolutionary interaction of genetically and culturally inherited traits (Feldman and Laland, 1996). This requires that change in cultural variation across generations can be modeled as an evolutionary system, including mechanisms for the generation of variation, the inheritance of information, and selection (*see* Cultural Evolution: Overview).

Gene-culture coevolution occurs when there is a statistical association between the differential fitness of genetic and cultural traits. This means that the fitness of genetic and cultural variants is nonindependent. In such cases, the evolution of phenotypic variation is underspecified by either a purely genetic or a purely cultural model of evolution, and the appropriate unit of selection is the combination of genetic and cultural variant, called the *phenogenotype*.

Originally, analytically tractable gene-culture coevolutionary models were developed from population genetic theory. For instance, the multilocus population genetic model was modified to consider the coevolution of genetic and cultural traits in place of multiple genetic traits at separate loci (Feldman and Zhivotovsky, 1992). Adjustments have been made to the genetic models to account for biases in cultural transmission that are unusual or not commonly applicable in a purely genetic model (*see* Cultural Evolution: Theory and Models). For instance, cultural information that is vertically transmitted from parents to offspring may in some cases be subject to parental biases, as can be found in many sex-biased cultural preferences. Cultural information also can be transmitted obliquely between generations such as from teacher to pupils, or horizontally, within a generation. This information, however, often is short-lived, such as fashions and fads, and may not persist long enough to affect genetic selection.

A gene-culture coevolutionary model can be developed by explicitly accounting for (1) the transmission of genetic and cultural variants between generations, accounting for phenogenotype mating probabilities and specific pathways of cultural and genetic transmission; and (2) the differential fitness of phenogenotypes. From these two components, the phenogenotype frequencies can be iterated across generations. Analytical work has generated predictions that are qualitatively distinct from most population genetic models of evolution, on account of both characteristic rates and patterns of cultural transmission (Feldman and Laland, 1996). Typically, cultural variants can spread much faster than genetic variants, and this can have a particularly strong effect on genetic selection. Below, I consider several cases concerning nutrition and disease, where cultural traits have enhanced the intensity of genetic selection. In contrast, a fast cultural response to a changing environment, such as the invention of health interventions, also can buffer or protect otherwise-deleterious genetic variants from purifying selection.

Patterns of transmission also can drive coevolutionary dynamics, as exemplified by the case of sex-biased patterns of cultural transmission. These can become statistically associated with genetic variants that have sex-biased expression, including those on sex chromosomes. An example of this effect is found in the coevolution of a cultural preference for sons over daughters with sex-ratio distorter genes, which can affect sex at conception by altering the proportion or viability of sperm carrying an X or Y chromosome. The models suggest that different types of cultural bias can affect the gene-culture coevolutionary dynamics (Kumm et al., 1994). The first case concerns parents that are inclined to increase their proportion of sons by a fixed amount while compensating for their offspring lost to infanticide by having additional children. This might occur if restrictions on the number of permitted offspring make it unlikely for the cultural bias to affect the total number of offspring (Laland et al., 1995). In this situation, the excess of males favors the mating success of females over males. This provides a selective advantage to female-biased distorter genes, which then can evolve to give a female-biased primary sex ratio (i.e., the sex ratio at conception before sex-specific mortality) and an unbiased adult sex ratio. This result is consistent with standard sex-ratio

theory. The dynamics may be different if parents attempt to bring their offspring sex ratio closer to their ideal preference but without having more children in response to offspring loss. Here, the models suggest that the primary sex ratio may become biased until it matches the male-biased preference exhibited in the adult sex ratio. Thereafter, there would be no further sex ratio adjustment by parents as the primary sex ratio matches their ideal preference.

This analytical modeling approach is particularly useful for generating qualitative predictions and understanding the principles of evolutionary mechanisms. This type of model was developed before sequencing of the human genome, and development of a haplotype map (HapMap), which collates patterns of human genetic variation. Since then, the opportunity to analyze real genome sequences has identified a considerable number of human genes that appear to have undergone recent and rapid selection. In many cases, the function and estimated age of these genes appear consistent with culturally derived modification of their selective environment. These functions include metabolism, immune response, exposure to extreme climates, brain function, and skeletal development (Laland et al., 2010 Richerson et al., 2010;). Large simulation studies can be developed to reveal the most likely mechanisms underpinning the geographically distributed gene frequency data (e.g., Itan et al., 2009).

In the Context of Evolutionary Anthropology

Three broad approaches to the study of the evolution of human behavior can be distinguished by their assumptions (Laland and Brown, 2011). This section provides brief descriptions of each and shows how gene-culture coevolution fits in with these schemes. The descriptions will be stylized in their brevity, and it can be argued that new generations of researchers are drawing across these fields to address evolutionary questions appropriate for the context in which they work.

Perhaps, the most high-profile approach to study the evolution of human behavior has been evolutionary psychology, which puts an emphasis on the genetic evolution of psychological adaptations. Commonly, the assumption is made that behavior and expressed preferences, for instance, in mate choice, reflect psychology that was shaped by natural selection in ancestral environments. By contrast, human behavioral ecology enquiry is focused on the effects of contemporary ecological variation on adaptive behavior (*see* Human Behavioral Ecology). Here, two common assumptions are that human behavior is currently adaptive (maximizes inclusive fitness), and that according to the phenotypic gambit, the mechanism underpinning the behavior largely can be ignored. Thus, optimality is considered not to be constrained by mechanism but rather reflects an often-complex trade-off resulting from the interaction of marginal fitness benefits in a local ecology.

By distinction from these schools, gene-culture coevolution is principally consistent with the third approach, which is the field of cultural evolution (Cavalli-Sforza and Feldman, 1981; Boyd and Richerson, 1985; Mesoudi, 2011). This field focuses on the micro (within population) and macro (between population) patterns of spread of socially transmitted information, in the form of ideas, beliefs, behaviors, and material culture. The cultural evolution approach does not require the evolutionary psychologists' prior assumption of past adaptation or the behavioral ecologists' assumption of optimality. Instead, heritable traits are assumed to be subject to descent with modification, through some form of social transmission and innovation. The framework accounts for demic selection, considered equivalent to natural selection, by differential survival and reproduction, and cultural selection, which accounts for differential adoption and reversion from the use of a culturally acquired trait (Feldman, 2008). Other standard evolutionary features – such as drift, migration, and trait linkage – also can be considered as appropriate.

The modeling of cultural evolutionary or gene-culture coevolutionary dynamics is typically distinct from memetics in that there is no need to consider the socially transmitted trait as a replicator; however, there does need to be some effect of social learning, such that the probability that a learner acquires a trait is affected in some way by the behavior of another individual or its products (e.g., learning directly from material culture). One focus of cultural evolutionary theory is to consider the impact of individual-level learning mechanisms and cognitive biases on population-level patterns of cultural evolution.

In some regards, gene-culture coevolution can be seen to share common aspects with both evolutionary psychology and human behavioral ecology. Of interest to evolutionary psychology, gene-culture coevolution models have been used to examine the genetic evolution of predispositions for various biases in social learning cognition, including nonlinear frequency-dependent biases, such as conformity (to copy the majority) and payoff-related biases, such as copying successful individuals. Indeed, it is thought that the gene-culture coevolution of prestige bias can result in the cultural evolution of maladaptive behavior (Boyd and Richerson, 1985), a result consistent with evolutionary psychology and not human behavioral ecology. Consistent with human behavioral ecology, however, gene-culture coevolution commonly predicts the evolution of adaptive behavior in contemporary environments, where genetic variation continues to evolve in response to culturally derived selective environments (the cultural process of modifying the selective environment can be referred to as cultural niche construction; Kendal et al., 2011).

The gene-culture coevolutionary framework is also consistent with a relatively recent cross-disciplinary perspective on evolutionary theory interested in the role of so-called soft inheritance, or nongenetic inheritance, on the evolutionary processes. Nongenetic modes of inheritance have been carved up in a number of different ways. For instance, while Jablonka and Lamb (2005) have distinguished epigenetic, behavioral, and symbolic forms of inheritance, niche construction theorists have highlighted ecological inheritance of semantic information and resources, including forms of cultural inheritance (Odling-Smee et al., 2003).

Soft inheritance is considered important in genetic evolution as it accounts for genetic selective environments that are a function of the distribution of soft-inherited variants, which

is not, itself, predicted by contemporary or ancestral genetic variation (if it were, then, a purely population genetic model would be most parsimonious). Thus, although it may be perfectly reasonable to distinguish the orthogonal questions of why a trait evolved and how it develops within an individual, the gene-culture coevolutionary perspective deals with cases in which the most parsimonious model for why a genetic trait evolved requires explicit accounting for the soft inheritance of acquired characteristics during development.

Nutrition

Perhaps the most well-known case of gene-culture coevolution, that of dairy farming and lactase persistence, provides a good example of fast cultural change having a dramatic effect on genetic selection. In young mammals, milk is an extremely important source of nutrients, including the carbohydrate, lactose, which is broken down into its constituent sugars by the enzyme lactase. After weaning, the capacity to absorb lactose does not continue in most mammals. Approximately 35% of humans worldwide exhibit lactase persistence beyond weaning, reaching high frequencies across different regions including parts of India, Europe, and parts of Africa (Gerbault et al., 2011).

Lactase persistence in these separate regions appears to be associated with different genetic single nucleotide polymorphisms (SNPs) affecting promoter activity of the lactase gene itself. Thus, it would appear that lactase persistence has evolved more than once. Estimates for the age of these alleles coincide approximately with the Neolithic, and their rapid increase in frequency to contemporary levels indicates unusually high strengths of selection. For instance, simulation modeling suggests that the European mutation ($-13910*T$), now commonly more than 90% in Northern European populations, arose only 7500 years ago in the Central Balkans (Itan et al., 2009).

A principal advantage of drinking fresh milk is its high calorific value, which may be particularly valuable when other food sources are low. It is also possible that there are advantages in northern climes where ultraviolet radiation (UVR) levels are low and vitamin D in milk can facilitate calcium absorption, and in malarial regions, by disrupting the pathogen. Furthermore, it is possible that drinking milk may act as a sign of prestige where status was linked with reproductive success in relatively hierarchical societies.

A diverse range of evidence from archaeological, phylogenetic, and simulation studies lend support to the culture-historical hypothesis, that dairy farming preceded the spread lactase persistence, rather than the alternative reverse-cause hypothesis, that dairy farming evolved in response to high levels of lactase persistence (Gerbault, et al. 2011). For instance, milk residues in Neolithic archaeological pottery typically predates or coincides with a low frequency of lactase persistence. Gene-culture coevolution most likely followed the original culturally derived selection for lactase persistence, leading to a reciprocal effect for the spread of dairy farming among populations in which lactase persistence was high.

Unsurprisingly, gene-culture coevolution is common between farming practices and domesticates, and dairy farming is no exception. For instance, a high correlation has been shown for the genetic diversity of cattle milk proteins with both the frequency of human lactase persistence and the distribution of early European cattle pastoralists. The inference is that dairy farming by early pastoralists in different regions may have resulted in high allelic diversity that then was protected from drift by continued strong selection for milk yield and protein composition (Beja-Pereira et al., 2003).

In addition to domesticated animals, the cultural evolution of crop use also has affected the genetic evolution of human capacity to digest new dietary components, such as the case of high-starch diets. It appears that the number of copies of the gene for salivary amylase, *AMY1*, which catalyzes the breakdown of starch into sugars, correlates strongly with the proportion of starch in the diet. For instance, amylase copy number was found to be high in samples from Japanese and Hadza, whose diets are high in rice and tubers, respectively, but low in the pastoralist Turkic Yakuts inhabiting the Sakha Republic in the North East Russian Federation, which typically has a high fat and protein diet based on milk, meat, and blood (Perry et al., 2007).

The between-group differences in *AMY1* copy number are significantly greater than is typical at other loci that vary in copy number. The number of copies appears to correlate with gene expression, thus assisting the digestion of starch. It is likely that gene-culture coevolution would ensue in light of the potential adaptive benefits of a high-starch diet, including a source of nutrition and protection against intestinal disease.

Disease

The preceding diet-related examples involve culturally driven positive genetic selection, resulting in adaptive behavior. In other cases, however, dietary preferences can be extremely maladaptive, resulting in the selection of compensatory mutations to counteract the effects of the cultural behavior. In an extreme example, the prion disease, kuru, was transmitted between members of the Fore linguistic group in the Eastern highlands of Papua New Guinea through their ritual practice of consuming deceased relatives at mortuary feasts. Recent research suggests that the kuru epidemic resulted in the selection of a resistant G127V allele of the host prion protein (PRNP) gene (Mead et al., 2009). Strictly speaking, this example deviates slightly from the topic, as the protein-based, rather than nucleotide-based, replication system of the prion disease makes this a case of protein-culture coevolution.

Although ritual and social norms can be important contributors to the genetic evolution of pathogens and host resistance, arguably the greatest culturally derived impact has been through farming and domestication. A classic example concerns malarial resistance. Kwa-speaking West African populations clear areas of forest to plant yams (Durham, 1991). Holes in these clearings from the removed trees fill with water during rains and provide a suitable habitat for mosquitoes to lay eggs and for their larvae and pupae to grow in the sunlit pools. Thus, their farming practice encourages the growth of mosquito populations, which are vectors for *Plasmodium* protists. Once adult, the female mosquitoes inject the microorganisms into the human host

while feeding on blood, resulting in malarial infection in both the liver and red blood cells.

The sickle-cell allele *HbS* is not common because it causes anemia through sickling of the red blood cells. Sickled cells, however, confer some resistance against malaria by clearing the parasite along with the defective red blood cells to the spleen. In homozygotes, where both copies of the gene are *HbS*, this disease can be fatal, following symptoms, including restriction of blood flow round the body and an acute drop in hemoglobin levels. The heterozygote form, in which only one of the two copies is *HbS*, confers resistance to malaria with only mild sickling effects. The frequency of the *HbS* allele appears to correlate strongly with rainfall and surplus water among Kwa-speaking yam-cultivating populations but not among neighboring populations that do not cultivate yams (Durham, 1991). Thus, the culturally transmitted farming techniques would appear to have influenced genetic selection for resistance. Furthermore, the high incidence of malaria also may have enhanced cultural selection for the farming of yams as these crops appear to counteract the effects of sickling by helping the production of hemoglobin (O'Brien and Laland, 2012).

Although culturally transmitted activities, such as farming, have affected genetic disease resistance in the host, it is unsurprising to find culture coevolving with the pathogens themselves. These are special cases of host-parasite coevolutionary systems, where the host phenotype is culturally, rather than genetically, derived. For instance, heavy use of antimalarials, such as quinine and chloroquine, have resulted in selection for resistant strains of *Plasmodium*, and in reaction, the development of new efficacious drugs. In some cases, cultural evolution in this parasite-host arms race has exploited solutions in a parallel race between the parasite and plant hosts. Plants, such as fava beans (broad beans), which have evolved oxidizing action that kills the plasmodia, are cultivated and administered to protect against malaria. The exploited plant defense mirrors antimalarial mechanisms found in sickle-cell and similar disorders, such as glucose-6-phosphate dehydrogenase (G6PD) deficiency, which also exhibit elevated oxidation within infected erythrocytes (Etkin, 2003).

Antagonistic gene-culture coevolution is evident between normative administration of antibiotics and the genetic evolution of bacterial strain resistance. Typically, arms races can ensue between the invention of antibiotics, such as penicillin and then vancomycin, which provide selective environments for resistant strains, for instance, of Enterococcus. Although the resistance typically incurs a fitness cost that is absent in strains that are susceptible to antibiotics, this cost is insufficient to outweigh the fitness benefits of protection from these drugs.

The evolution of resistant strains can result not only in investment to develop new drugs, but also to alter normative prescribing practices, in an attempt to reduce the concentration of antibiotics in the environment. Models predict that when resistant-strain frequency is high, discouragement of high-prescribing practices can maintain bacterial strain polymorphism in cases in which it otherwise would not be expected. A strong conformist bias toward high antibiotic use, however, can lead to the fixation of the resistant strain. This work shows how cognitive biases affecting cultural transmission have population-level consequences for the trajectory of gene-culture coevolutionary dynamics (Boni and Feldman, 2005).

The gene-culture coevolutionary dynamics also can be affected by the trajectory of bacterial evolution. For instance, resistant strains can evolve compensatory mutations that retain their resistance but at a reduced fitness cost. Although antibiotic use encourages selection first for resistance and then for these new compensatory strains, a subsequent reduction in antibiotic use does not necessarily lead back to the evolution of the susceptible strain. This is because, in the absence of antibiotics, the fitness of both the compensatory and susceptible strains is greater than that of the original resistant strain. If the compensatory strain can only evolve back to the susceptible strain via an intermediate resistant but non-compensatory strain, the evolutionary trajectory would have to pass through what is effectively a valley in the fitness landscape (Bergstrom and Feldgarden, 2008). It has been shown that escape from the compensatory peak, through what is known as an 'evolutionary lobster-trap' (easy to get under high concentration of antibiotics but difficult to leave under low concentration of antibiotics) is possible under some conditions through a process called stochastic tunneling, which relies heavily on random sampling effects to succeed (Tanaka and Valckenborgh, 2011).

Cumulative Cultural Evolution

The examples discussed thus far typically are characterized by strong culturally derived selection over sufficient generations of the genetically evolving organism. This type of cultural dynamic is characteristic of a unique facet of evolution in the hominin lineage called cumulative cultural evolution. Here, learned information is passed across generations and developed so that cultural traits typically become more efficient or more complex and beyond the capacity for individual invention within a lifetime. A key feature of this process is that, in general, significant information is not lost between generations, but rather 'ratchets up' with its inheritance and modification across multiple generations (Tennie et al., 2009). This process can provide large changes in the selective environment for genetic evolution, which are sustained across sufficient generations for fast genetic evolution to occur.

In the absence of any ratcheting effect, a socially transmitted trait would risk dissolving away to extinction, particularly in variable environments. Thus, it is perhaps unsurprising not to find strong evidence for gene-culture coevolution in nonhuman primates, where cumulative culture appears to be absent, and thus culturally modified genetic selective environments may not be sustained across many generations in variable environments (*see* Social Learning and Culture in Nonhuman Organisms). In the hominin lineage, however, cumulative cultural evolution is likely to have ensured that the modified genetic selective environments are retained across generations, and further, that the magnitude of selection may be enhanced as the cumulative process proceeds.

Overall, a gene-culture coevolutionary dynamic that involves cumulative cultural change can undergo what is effectively a bootstrapping process, where the *rate* of cumulative cultural evolution is affected by coevolving genetic traits.

For instance, the cumulative cultural evolution of adaptive technology and societal norms in the hominin lineage may have affected, and been affected by, the capacity for social learning. The coevolution of social learning and adaptive information is integral to a number of theories exploring the evolution of human behavior, social systems, and technology, such as the cultural niche hypothesis (Boyd et al., 2011).

The capacity for the cumulative cultural evolution of technology has allowed humans to colonize diverse and extreme environments, resulting in genetic selection. For instance, populations living on the Tibetan and Andean plateaus carry several genes that are likely to have undergone selection in response to high-altitude hypoxia. Andeans have enhanced oxygen saturation compared with individuals from sea-level populations, but Tibetans appear to have elevated lung capacity, breathe more rapidly, and exhibit high levels of nitric oxide, which dilates blood vessels to enhance blood flow (Brown, 2012).

In response to migration and colonization of a diverse range of environments, gene-culture coevolution most likely contributed to the evolution of various external human phenotypes, such as hair color, skin color, and stature, through degrees of culturally affected sexual selection and natural selection. For instance, sexual dimorphism in skin pigmentation may have been enhanced in some populations by male cultural preference for lighter female skin (Jablonski and Chaplin, 2010). Arguably, however, a stronger predictor of skin pigmentation is latitude, or more specifically UVR, which surely was affected by culturally transmitted patterns of migration and the cultural evolution of tool kits allowing humans to have colonized novel environments. Dark and tanning skin most likely evolved to protect against UVR-mediated folate depletion, which can lead to fetal neural tube defects. By contrast, human migration to high latitudes may have resulted in selection for low pigmentation to enhance UVR-mediated vitamin D production in the skin, which has many important functions in the body, including bone metabolism and immune response (Jablonski and Chaplin, 2010).

The importance of cultural learning in hominin evolution has been situated within a broader context, referred to as the sociocognitive niche, which considers five principal components: 'cooperation, egalitarianism, mindreading, language, and cultural transmission' (Whiten and Erdal, 2012: p. 2119). The interactions between these facets often have been considered within a gene-culture coevolutionary framework. For instance, hypotheses have suggested a coevolutionary relationship between symbolic representation associated with material culture and technological development, and the genetic evolution of the parietal cortex, which can affect the capacity for language and motor-skills when using tools to solve tasks (Iriki and Sakura, 2008).

The capacity for cooperation is on many researchers' shortlist of key features affecting the hominin evolutionary trajectory (*see* Human Cooperation, Evolution of). For instance, ostensive sharing of learned information within and between societies that extends beyond close kin groups may catalyze the cumulative cultural evolution required for adaptive behavior in novel environments. One gene-culture coevolutionary proposal for the evolution of cooperation concerns the effect of between-group patterns of cultural evolution found in cultural group selection. The suggestion is that there can be cultural selection between groups, whose distinctions are retained by local social norms and cultural group markers, through differential normative practices affecting demographic and economic success, success in warfare, and prestige bias encouraging the adoption of norms of individuals from successful groups. These patterns of cultural evolution, which often may involve selection on adaptive cooperative norms, then may influence the genetic selection of predispositions that support such norms, such as prosociality, character virtues (e.g., honesty and trustworthiness), norm internalization, and conformity (Boyd et al., 2005; Henrich and Henrich, 2007).

Simulation models have shown that normative variation across groups can suppress genetic diversity at neutral loci and that this may explain relatively low-estimated Pleistocene hominin genetic diversity compared with that in extant great apes. Assuming both selective and neutral genetic and cultural loci, if there is a high threshold of cultural similarity required for migration between groups in a metapopulation, genetic diversity initially accumulates as cultural distinctions limit gene flow between groups. This is followed, however, by a sharp reduction in genetic diversity of neutral loci, as daughter groups of the most successful group sweep across the metapopulation (Premo and Hublin, 2009).

Conclusion

Gene-culture coevolution most likely played an important role in the evolution of modern humans and continues to do so today. In fact, it is possible that gene-culture coevolutionary dynamics that resulted from the advent of farming have yet to reach their zenith. Recent work suggests that although selective sweeps of beneficial mutations, spreading rapidly to fixation in a population, are not particularly frequent (Ryan et al., 2011), it is estimated that approximately three-quarters of all autosomal protein-coding single nucleotide variants, most of which were deleterious, evolved within the last 5000–10 000 years (Fu et al., 2013). Purifying selection (acting on deleterious alleles) has been unable to keep up in the face of culturally mediated exponential population expansion, from 5 million to 7 billion people, during this period. As a consequence, there is a high level of rare functional genetic variation – for instance, in relation to disease susceptibility – and the potential for adaptive evolution in our rapidly changing, culturally constructed, selective environments.

Gene–Environment Interactions in Health and Well-Being

Jason Schnittker, University of Pennsylvania, Philadelphia, PA, USA

Abstract

Gene–environment interactions represent an important frontier in science and play an increasingly important role in forging interdisciplinary research. This article outlines what gene–environment interactions are, illustrates the different types of gene–environment interactions, distinguishes gene–environment interactions from gene–environment correlations, and reviews the findings of a number of exemplary studies. It also discusses some of the difficulties in studying gene–environment interactions and some of the reasons for lingering uncertainty in the empirical literature.

Enthusiasm for identifying the genetic determinants of health has quickly developed into the pursuit of discovering gene–environment interactions. The study of gene–environment interactions was hastened by the development of molecular genetics in the 1980s and 1990s and accelerated in recent years by the expansion of high-throughput genotyping technologies (Rutter et al., 2006). Although much of the early research sought to identify a single gene or small set of genes that caused a given condition, it quickly became apparent that genetic influences were much more complex and probabilistic (Kendler, 2005). Indeed, the additive effects of even genes that have survived replication are generally quite small, so that, for example, the odds of developing a psychiatric disorder increases by less than a factor of two (Kendler, 2005). Thus, efforts to identify 'a gene for' a given condition have largely disappeared.

Against this background, research has turned to the study of gene–environment interactions. The study of such interactions allows researchers to assess under what conditions genes do or do not matter, rather than how much they matter on average. In addition, the study of gene–environment interactions allows researchers to address a well-known feature of environmental risk: even for the strongest environmental risk factors, such as stress in the case of psychiatric disorder (Kessler, 1997) or smoking in the case of heart disease (Talmud et al., 2000), variation in response to these risks is enormous. Some individuals seem unusually robust to stress and see no increase in depression as a result, for example, whereas others are greatly affected by stress. Genes provide a potentially powerful explanation for this variation. At present, the gene–environment literature represents both an exciting and promising frontier and a site of ongoing controversy, much of it stemming from the uncertainties of common research designs.

Definition of a Gene–Environment Interaction

The study of gene–environment interactions is concerned with joint influences: with how variation in genes leads to different responses to environmental exposures or, conversely, how variation in environmental exposures leads to different effects of genes (Hunter, 2005; Ottman, 1996). In the study of interactions, the environment is defined broadly and can refer to proximate influences that are close to or within the individual, including chemical or biological exposures; more distal influences that are features of the social environment, including living in a high-poverty neighborhood or losing a job; or intermediary influences, such as stress, which link the environment and the person. The genetic element of the interaction is usually defined in terms of specific genes, but can also refer to generic and unspecified genetic influences, as in the case of research employing the classic twin design to examine variation in the degree of heritability as a function of measured environmental influences (Plomin et al., 2005). Because twin studies speak only to nonspecific genetic influences, researchers tend to regard molecular studies of gene–environment interaction as more compelling, although twin studies provide an important foundation to molecular research and, indeed, have set the stage for the modern study of interaction. Another method for detecting interactions is to explore interactions between a phenotype that is unambiguously the product of genes and an environment, as when research explores the effects of sunlight on skin cancer among fair- and dark-skinned persons, but interactions of this sort are necessarily focused because the number of phenotypes that are unequivocally genetic is small.

A generic definition of a gene–environment interaction does not describe the many varieties of interaction that are possible. In general, there are three types, and differentiating among them is an important if often-overlooked activity (Ottman, 1996; Ottman and Rao, 1990). The three types are represented in **Figure 1**, based on the framework of Ottman (1996). In Type A, genetic influences moderate the effects of an environmental factor, but genes have no influence among individuals not exposed to the relevant environmental factor. In Type B, the parameters are switched. An environmental factor moderates the influence of genes, but the environment has no direct effect on its own. In Type C, the presence of both the relevant genes and environments is necessary to realize an effect. Individuals without the relevant genes will not be affected even in environments conducive to the outcome, and individuals unexposed to the relevant environment will not be affected even if they have the relevant genes.

Within these three types of interaction, there are further refinements, as outlined by Shanahan and Hofer (2005). In these cases, the type of interaction reflects the magnitude and direction of the moderation. First, the environment may 'trigger' a genetic vulnerability, as when stress activates

Figure 1 Three types of gene–environment interactions. Adapted from Ottman, R., 1996. Gene–environment interaction: definitions and study design. Preventive Medicine 25, 764–770.

a predisposition for depression as in the case of the diathesis–stress model (e.g., Rende and Plomin, 1992). Second, the environment may compensate for a genetic vulnerability, as when an enriched environment prevents a genetic predisposition for depression from materializing (e.g., Caspi et al., 2003). Third, the environment may reduce the impact of genetic factors by limiting opportunities, such as in the case of social control, as when some individuals are born with a genetic predisposition for alcoholism but laws, rules, or norms prevent alcohol consumption altogether or severely curtail its use (e.g., Koopmans et al., 1999). Fourth, the environment may accentuate positive genetic influences, as when genetic influences on educational attainment grow stronger as the educational system is opened up to a larger fraction of the population (e.g., Heath et al., 1985).

A gene–environment interaction is different from a gene–environment correlation, although both are features of gene–environment interplay. A gene–environment correlation pertains to when genetic influences are related to an individual's exposure to particular kinds of environments, as when an environmental exposure depends on genes. In this case, there is some genetic control over environmental exposure. For example, genes might increase exposure to stress by way of personality, which is at least partly heritable: a neurotic person may put themselves in more stressful situations. This implies an association between genes and environments: genes affect environments, but it does not imply that the effects of genes are contingent on the environment, as in a gene–environment interaction. Understanding correlations of this sort is important, but correlations reflect a different set of processes than interactions. A correlation can emerge in three ways: first, if individuals are put into environments that are related to their genes but not by virtue of their own behavior, as in the behavior of parents directed toward their biological offspring (a passive correlation); second, if individuals select themselves into an environment based on their genes (an active correlation); or, third, if individuals induce in others behavior that is related to their genes, as when a depressed person induces negative behavior from their spouse because of their depression (an evocative or reactive correlation) (Plomin et al., 1977). The range of environments affected by gene–environment correlations is quite large, reflected in the heritability of many measures of stress commonly regarded as 'environmental' (Kendler and Baker, 2007). Furthermore, there is substantial heritability even in more upstream measures of the environment, including socioeconomic status and social support (Schnittker, 2008a). Ideally, studies of gene–environment interactions should insure that the gene being studied is not correlated with the environment being studied or try to break any correlation using an appropriate research design (see Liu et al. (2004) on research designs to detect interaction). Nevertheless, the complexity of the processes behind gene–environment correlation makes this difficult, and the empirical evidence for gene–environment interactions is complicated as a result.

Empirical Evidence for Gene–Environment Interactions

There are abundant studies of gene–environment interactions now in the literature. Below is a summary of only a few such studies. These studies were selected because they either are emblematic of the literature or have been subject to widespread replication. These studies focus on psychiatric disorders, a topic for which the study of interactions has been particularly active (Hamer, 2002). Furthermore, these studies represent studies of humans. It is notable, however, that there is a parallel literature on gene–environment interactions among nonhuman animals, and these studies do not suffer from some of the research design problems discussed shortly. Studies of model organisms allow for strict manipulation of both environments and genotypes and can speak effectively to gene–environment interaction among humans (McClearn, 2004).

In a landmark investigation, Caspi et al. (2003) demonstrate an interaction between life stress and polymorphisms in the promoter region of the serotonin transporter gene (5-HTT). The study focuses on life stress and depression, but is expansive with respect to both concepts. With respect to stress, it explores interactions with both stressful life events and childhood maltreatment, and with respect to depression, it explores diagnosable depression, depressive symptoms, and suicidality. Caspi and colleagues find that stressful life events increase depression among those with a copy of a short allele of the 5-HTT promoter polymorphism, but not among those with two copies of the long allele (who made up 31% of the sample). On its own, the serotonin transporter gene has only a marginally significant main effect, although stress has a highly significant main effect, reflecting the genetic composition of the sample and the well-known effects of stress. The gene–environment interaction is specific to 5-HTT. Interactions with a related gene affecting monoamine oxidase A (MAOA) were insignificant.

The Caspi study received a good deal of attention and was widely embraced in scientific circles. *Science* declared it the second most important scientific discovery of 2003,

characterizing it as a 'huge catch' in a sea of potential interactions (Holden, 2009, p. 1628). The study received a good deal of media attention as well (Horwitz, 2005). There were several reasons for this enthusiasm. For one, the interaction was entirely plausible. The widespread use of serotonin-specific reuptake inhibitors in the treatment of depression and the well-established relationship between stress and depression gave the study a biologically credible mechanism wed to a clear environmental risk. In addition, the study helped resolve the uncertainty surrounding the main effect of 5-HTTLPR, which, to that time, had shown only inconsistent effects. The study fit quite well in the existing research, even as it subtly shifted the paradigm.

A host of related studies soon followed. Related studies looked at other disorders and different biological processes, but reached similar conclusions regarding the general importance of gene–environment interactions. Ducci et al. (2008), for example, explore an interaction between childhood sexual abuse and a functional MAOA locus, predicting alcoholism and antisocial personality disorder among adult women. They find a significant interaction, such that sexually abused women who were homozygous for the low-activity allele had higher rates of alcoholism and antisocial personality disorder than abused women who were homozygous for the high-activity allele. Among women who were not sexually abused, the MAOA genotype had no relationship with these disorders, revealing, in this way, an especially strong contingency.

Young et al. (2007) expand the potential range of interactions with the serotonin transporter gene 5-HTT. They do so by exploring its relationship with the limbic system and cognition, rather than a single specific psychiatric disorder. They find an elevated number of pulvinar (the medial part of the posterior end of the thalamus) neurons in subjects with two short copies of the 5-HTTLPR allele, which may heighten the impact of aversive emotional stimuli in the limbic system and, in turn, increase the risk for major depression, bipolar disorder, schizophrenia, and other psychiatric disorders. Indeed, the authors speculate that excessive levels of limbic activity increase fear, anxiety, and cognitive interference, setting the stage for a variety of interactions relevant to emotion and behavior.

The appeal of studying gene–environment interactions has extended to more traditional social sciences as well, including sociology, political science, and economics (e.g., Benjamin et al., 2012). Although traditional social sciences continue to use the twin design, molecular studies are appearing as well. In an article appearing in the *American Journal of Sociology*, for example, Pescosolido et al. (2008) explore interactions between the GABRA2 gene and assorted features of the environment in predicting alcoholism. Although generally interested in the effects of social position and resources, the authors test two specific interactions, both of which are significant. They find that family support attenuates the relationship between GABRA2 and alcoholism, while childhood deprivation accentuates it. Among those with low genetic risk, childhood material deprivation is unassociated with alcohol dependence, meaning the effect of childhood background depends entirely on a genetic predisposition. Family social support has a stronger relationship with alcohol dependence among those at high genetic risk, but the relationship is found even among those at low genetic risk. The main effect of GABRA2 is significant for the full sample, but further analyses show that this effect is apparent only among men and, in any case, is not terribly large. These assorted interactions are compelling as evidence for gene–environment interaction, but they are perhaps equally compelling for introducing some conceptual ambiguity. For instance, Pescosolido and colleagues find an interaction with family support, but not an interaction with friend support, implying something more than a generic effect of social support or stress in moderating genetic influences. The authors advance a network-based explanation, but future research will have to explore the mechanisms further.

Other studies do not explore interactions between specific genes and the environment, but rather explore the role of the environment in reducing or increasing the heritability of a phenotype, using the classic twin design. Such a design asks a question similar to that asked by molecular studies, but provides a different type of answer. In general, heritability is defined as the fraction of variance in a phenotype that can be explained by genetic variation in a population. Multivariate models allow researchers to ask whether this fraction is more or less dependent on other covariates. For example, research has explored the degree to which individual differences in cognitive ability can be explained by genetic influences more in low- or high-socioeconomic environments. In this vein, Tucker-Drob et al. (2011) find a significant gene–environment interaction that emerges as children develop. At age 10 months, genes account for a small amount of the variation in mental ability, and socioeconomic status is unrelated to ability. By the age of 2 years, however, there is a large gene–environment interaction. Among children in high-socioeconomic-status homes, genes account for nearly one-half of the variation in mental ability. Among children raised in low-socioeconomic-status homes, however, the environment is the dominant influence, with genes accounting for a very small fraction of the variance. Findings of this sort are consistent with the idea that genetic influences emerge in reciprocal interactions between an individual and her or his environment, but they call for a better understanding of the process. In the case of cognitive abilities, it is likely that low socioeconomic status impairs a child's ability to interact with environments that foster intellectual growth, resulting in suppressed genetic influence, whereas high socioeconomic status allows children to seek out environments consistent with their genetic endowments (see Scarr and McCartney, 1983).

Studies using the twin design are perhaps more common among social scientists than are molecular studies, which may explain their generally stronger engagement with the environment. Indeed, studies of this sort embrace an unusually wide assortment of environmental influences, including influences related to time period and culture. Boardman et al. (2010), for example, explore trends in the heritability of smoking and demonstrate how these trends can be explained in reference to the history of smoking-related knowledge and policies. In particular, they find strong genetic influences on smoking among those born in the 1920s, 1930s, and 1950s, but weak genetic influences among those born in the 1940s and 1960s. These birth cohorts map approximately onto certain historical events: the publication of the first Surgeon General's

Report in 1964 increased genetic influences, but subsequent smoking legislation decreased genetic influences. These countervailing effects reflect different processes. On one hand, the public acceptance of the Surgeon General's Report left the population of remaining smokers disproportionately reflective of those with a strong genetic proclivity to smoke, as those who smoke only in social settings will find it easier to quit in light of the recognition that smoking is harmful. On the other hand, legislation increased social control over smoking and, thereby, restricted variability in smoking among genetically diverse individuals (see Shanahan and Hofer, 2005). In general, genetic influences increase when a behavior becomes more widespread and social sanctions are reduced, which is what occurred in the case of smoking.

Related to this interpretation, Boardman et al. (2008) also show that genetic influences on smoking among adolescents are higher among those who attend schools where popular students smoke. A similar result was produced by Heath et al. (1989), albeit for a different outcome and a different environment. They find the heritability of alcohol consumption is lower in married than in unmarried women, reflecting differences in social control. Similar results have been found with respect to religious upbringing, which suppress genetic influences on alcohol consumption relative to nonreligious upbringings (Koopmans et al., 1999).

Findings of this sort can even be expressed with respect to the influence of culture. Dunne et al. (1997), for example, explore the heritability of sexual behavior and find differences between cohorts that can be accounted for by trends in sexual tolerance. Among those born in the early twentieth century, the heritability of age at first intercourse was relatively low, approaching zero in men. Among those born after 1950, however, the heritability of sexual behavior climbed enormously, reaching 72% for men. Similar results have been reported with respect to fertility, suggesting a process whereby a decline in social sanctions and improvements in birth control allow individuals to act on their genetically influenced preferences in a way that was not possible in earlier eras (Kohler et al., 2004).

Challenges in Identifying Gene–Environment Interactions

Although there is sufficient evidence to suggest that gene–environment interactions are ubiquitous and much of the evidence is compelling from the standpoint of social theory, there are numerous methodological challenges in studying interactions. The replication record of gene–environment studies is far from perfect. In a meta-analysis of the Caspi study, Risch et al. (2009) find little evidence for an interaction between 5-HTT and stressful life events, prompting some to encourage psychiatric genetics to go 'back to the drawing board' with respect to genes (Holden, 2009, p. 1628). In their meta-analysis, Risch and colleagues find a relationship between the number of stressful life events and depression, but no association between 5-HTTLPR and depression, either as a main effect (which Caspi and colleagues found as well) or as an interaction with stressful life events. Others have likewise concluded that evidence for an interaction is largely consistent with a chance finding (Munafò et al., 2009). These meta-analyses also suggest some limitations that were not anticipated in the initial study and are difficult to explain. For example, Eley et al. (2004) find a significant interaction, but only for girls. The conclusion of these meta-analyses is disputed. Some question the set of studies they use, which represent only a fraction of the total number of studies available. Analyses that include a wider set of studies find more evidence for an interaction (Karg et al., 2011). Regardless of whether the interaction is significant or not, it seems clear that the particular gene–environment interaction documented by Caspi and colleagues – and, indeed, virtually all other interactions documented in the literature – is sensitive to study design. The question is where exactly this sensitivity comes from and what it means. It is premature to disregard gene–environment interactions altogether, although it is important to reconsider what interactions reveal.

Part of the problem stems from our lack of understanding of genes themselves. The main effects of genes are generally not well understood, undermining the ability of researchers to evaluate the significance of interactions. In the case of psychiatric disorders, the effects of genes are often not replicated, even prior to testing interactions: genes with significant average effects in one study are not significant in another. This lack of replication reflects many things, but it at least partly reflects the presence of false negatives driven by underpowered studies (Lohmueller et al., 2003). The presence of weak effects in a small sample diminishes the capacity of researchers to evaluate interactions. Part of the problem also reflects how environments can be the product of genes. Exposure to stressful life events can be influenced by genes, and most studies of gene–environment interaction do not control for a sufficient number of genes to eliminate this possibility entirely. If the environment reflects the influence of genes, the apparent effects of stressful life events could reflect the effects of other unmeasured genes and, thus, the apparent gene–environment interaction could reflect a gene–gene interaction instead. In their study, Caspi and colleagues do, in fact, find a relationship between genes and stress: those with the short alleles that increase responsiveness to stressful life events also report more stressful life events. Caspi and colleagues make a logical case for a gene–environment interaction over a gene–gene interaction on the basis of time ordering and information regarding the onset of depression. They reason that if the gene–environment interaction they find reflects a gene–gene interaction instead, then they would find an interaction between 5-HTT and life events even for events that occurred after the onset of depression. However, they did not find this interaction in their data.

Some studies have attempted to subject gene–gene interactions to a more direct empirical test by using exogenous sources of environmental stress. In a sweeping study, Conley and Rauscher (2010) attempt to replicate several gene–environment interactions found in the literature using a combination of twin data, molecular information, and birth weight. The use of twins provides substantial leverage over unobserved genetic characteristics by providing a natural experiment: twin births effectively randomize a strong environmental influence, fetal position, which results in birth weight differences among genetically identical

twins who grow up in very similar environments. In this way, it is possible to use birth weight as an exogenous environmental insult within twin pairs, if one accepts that birth weight represents a conceptually meaningful product of the environment and not just a statistically exogenous one. Using this method, Conley and Rauscher find no evidence for gene–environment interactions or for the main effects of genes. In the case of their replication of the Caspi study, they find an interaction in the opposite direction. To be sure, birth weight is not stress per se – replication demands a strict mapping with the initial study – but it is an indicator of environmental insult that will, by design, be uncorrelated with genetic influences, an aspect of the study that is not possible in most observational studies.

Part of the problem with replication also stems from inconsistent measures of the environment. In reference to studies of stress and 5-HTT, Monroe and Reid (2008) characterize the measures of stress as 'ad hoc' (p. 947) and argue that the inconsistency this introduces is one reason for the apparent lack of reproducibility. Studies that measure stress in different ways do, indeed, reveal different interactions. For example, studies have produced stronger results when using objective measures of stressful life events rather than self-reports (Karg et al., 2011). Replication is also stronger for mildly threatening events than for severely threatening events (Kendler et al., 2005). Similarly, replication is stronger when exploring chronic stress than when exploring eventful stress (Karg et al., 2011). Even within the set of studies that use a simple count of the number of stressful events, there are inconsistencies that are difficult to explain. A review of studies attempting to replicate Caspi and colleagues' results found widely varying time frames for measuring stress, ranging from 1 month to lifetime measures (Monroe and Reid, 2008). The rapid decay of the effects of stress on depression introduces considerably heterogeneity between these measures. Interestingly, however, the intuitions that scholars have regarding gene–environment interactions may not align neatly with our understandings of how the effects of stress decay. In replicating the Caspi study, Wilhelm et al. (2006) use both a five- and one-year window for life events and find significant interactions only for the longer window, even though the main effects of stress operate over a shorter time frame. Without a well-characterized measure of stress wed to a robust theory of interaction, it is impossible to interpret these inconsistencies. Researchers may be tempted to conclude that gene–environment interactions are too complicated to be meaningful. This inconsistency also betrays the lack of engagement of the literature with the long-standing literature on stress. In fact, research knows a good deal about stress and how it can be measured (e.g., Brown and Harris, 1978). At present, this literature is not well integrated with the gene–environment literature.

The inconsistent measurement of stress reflects a more general problem. In general, the empirical characterization of the environment in gene–environment research is often abstract, which contrasts sharply with the very specific measurement of genes (Rutter et al., 2006, p. 251). Studies of the moderating influence of socioeconomic status, for instance, often use omnibus measures (i.e., measuring various factors together; Tucker-Drob et al., 2011) and, thereby, obscure variation in the effects of different components, such as income, education, and occupation. Related to this is a problem specific to studies documenting change in the heritability of a phenotype between cohorts. It is common to argue that an increase in the heritability of a phenotype such as fertility or sexual behavior reflects a decline in social control. This is a plausible interpretation, but studies rarely measure social control directly and, instead, infer it from historical events or social trends. Studies of this sort provide an invaluable set of observations and findings, but their interpretations are often incomplete in ways that prevent the development of a fully realized theory.

The Reception and Interpretation of Genetic Research

No review of gene–environment interactions would be complete without discussing the reception of gene–environment research in public opinion. The social and historical background to gene–environment research is, of course, controversial. Early eugenic interventions cast genetic influences in a deterministic fashion and linked genes to the inferiority of some populations (Duster, 2003). Although eugenic research has been discredited and the conceptual sophistication of the literature has advanced considerably, vestiges of the controversy remain in the distrust that some scientists maintain regarding genetic research (Rutter, 2006). Gene–environment research provides a potential antidote to this concern because it, in principle, puts genes and environment on the same footing. Yet there is also a lingering tendency to regard the influence of genes as somehow superordinate to those of the environment, especially in popular media. In particular, there is a tendency to regard gene–environment research as revealing more about genes than the environment, even if by definition an interaction means genes and environments cannot be interpreted apart from each other. In a review of media coverage of the Caspi study, for example, Horwitz (2005) finds a systematic emphasis on genetic influences rather than environmental influences, with much of the coverage referencing the possibility of finally discovering a gene for depression. Recognizing the interpretive difficulties in reporting gene–environment research, some scientists have encouraged standards for the presentation of results, disambiguating the influence of main and joint effects in tabular format (Botto and Khoury, 2001).

The public reception of genetic knowledge has its own complexities. For some advocates, the rise of research on genetic influences held the promise of finally reducing the stigma associated with certain health conditions, especially psychiatric disorders. The assumption was that identifying genetic influences would eliminate the idea that those who were afflicted brought the condition on themselves or were too weak to cope. Public opinion data reveal that the public is more receptive to genetic arguments than they were in the past, but that genes do little to obviate the public's insistence on personal responsibility. In particular, the public is increasingly likely to believe psychiatric disorders are caused by genes, in tandem with family background and stress, which they have long recognized as relevant (Schnittker, 2008b). This understanding is not inconsistent with the scientific understanding of psychiatric disorders. Nevertheless, the stigma surrounding psychiatric disorders has not changed

and for some psychiatric disorders, such as schizophrenia, the growing acceptance of genetic arguments may have accentuated the stigma by making those with schizophrenia appear even more dangerous. In the area of gene–environment interactions, there is much left to learn.

Gene–Environment Interplay

Abstract

Although the social and behavioral sciences were long divided over the relative sway of nature and nurture, an emerging field of inquiry, the study of gene-environment interplay, seeks to undermine these distinctions by looking at how these influences on social and behavioral outcomes are interdependent. This article provides a brief overview of three forms of gene-environment interplay: additive genetic and environmental effects, gene-environment correlations, and gene-environment interactions. A distinction is drawn between statistical genetic and molecular genetic models of gene-environment interactions. Finally, a variety of models of gene-environment interactions are described, and the limitations of current research on gene-environment interplay are briefly assessed.

Introduction

The days in which the social and behavioral sciences were polarized by debates concerning the sway of nature and nurture over human behavior are, and ought to be, long past. It is beyond serious debate that many most behaviors are influenced by genetic factors, and it is equally obvious that few behaviors and traits of interest to social scientists are solely biologically determined. It was not always thus. Sociologists have long concerned themselves with the intergenerational transmission of behavioral traits (e.g., similarity of smoking among grandfathers, fathers, and sons) without making serious efforts to link this common behavior to common genes within families. In parallel, biological scientists frequently argued with little persuasive evidence that biological influences on behavior were responsible for the majority of variation in human behaviors.

Rather than torturously resurrecting these tired debates, this article provides an overview of a nascent yet exciting field of inquiry: gene–environment interplay. The field of gene–environment interplay concerns itself with the myriad ways in which genetic and environmental processes function interdependently. That is, it is rarely the case that one can account for differences in behaviors because of nature or nurture. In fact, it is increasingly obvious that nearly all human traits are influenced by nature and nurture. This approach has grown exponentially in popularity in the past 20 years. Yet it is not a mere academic fad. Rather, the promise of gene–environment interplay research is that it provides a framework for thinking about social and behavioral science that is integrative, not oppositional, and based on evidence, not assumptions. This approach to behavioral and social science has the potential to bring together valuable lessons from sociology, demography, economics, anthropology, political science, genetics, development, and neuroscience to provide a framework for thinking about humans as both biological and social beings. Although it will likely not be the dominant framework in any other subfield of social science, it has the potential to inform the thinking of all fields of social scientific inquiry.

For example, consider the results of a paper by Boardman et al. (2010) that are summarized in **Figure 1**. In this study, the researchers used samples of adult twins to estimate the extent to which genes influenced the likelihood that an individual would become a regular smoker by the age of 30. As shown in this figure, genetic factors were very important for the earliest cohorts but became increasingly less relevant. For those born in 1942, genes had virtually nothing to do with whether or not they became regular smokers. This birth cohort was also at the prime age of smoking onset when the 1964 Surgeon General's report on smoking was released. Following the release of this report genes become more important over time because the composition of smokers began to change such that entry into smoking status was increasingly among those for whom smoking onset was being pushed by genetic factors. However, this changes noticeably when increasingly restrictive social policies were instituted the limited entry among many individuals such

Figure 1 Birth cohort differences in the genetic effects on regular smoking (Boardman et al., 2010). *Note*: Data come from the 1995 National Survey of Midlife Development in the United States (MIDUS) (Brim et al., 1996). Estimates are obtained from a series of multivariate Cox regression models with shared frailty among twin pairs, and they describe the heritability of regular smoking for each year of birth. The bars around each point estimate describe the 95% confidence intervals for each year. These confidence intervals were bootstrapped from 200 runs for each zygosity using the coxph package for R 2.7.1 for all years between 1922 and 1968. Each birth year contains the 4 years before and after and thus describes a 9-year window for the estimated genetic influences on smoking at that time.

that genes, again, became less relevant for entry into the smoking status. This example illustrates that it is very difficult to ever say for certain if the reason that people smoke is because of nature or nurture. The relative influence of each factor is always changing so your answer depends on when, where, and for what behavioral trait one is interested in.

Genetic Research Terminology

First, we provide some very brief background in the terminology of genetics for those who are not familiar with this field. The human *genome* consists of an ordered series of paired *nucleotides* in two matching strings, arrayed in a double helix as deoxyribonucleic acid, or DNA, in 23 *chromosomes*, or discrete strands of DNA. As shown in Figure 2, cells in the human body contain each of these 23 chromosomes. There are four nucleotides in the human genome: adenine (A), thymine (T), guanine (G), and cytosine (C). These are paired together determinatively, such that A is always paired with T and G with C. A *polymorphism* is a section of the genome in which variations in this base pair sequence are found between humans; a *single nucleotide polymorphism* (SNP) occurs when this consists of a single base pair difference. The different proteins are illustrated by the different colors in Figure 2. This variation in the human genome produces *alleles*, or DNA sequences which vary among humans. The observed combination of alleles at a location in one's genome is known as one's *genotype* at that location. Genetic researchers frequently seek to link genotypic variation to variation in *phenotypes*, which is the biological term for an organism's characteristics or traits. Phenotype is a synonym for 'outcome variable' in social scientific research.

Figure 2 Structure of the human genome: the key components. *Note*: This figure was taken from the collection of figures organized by the National Institute of General Medical Sciences: http://images.nigms.nih.gov/index.cfm?event=doSearch&searchTerm=genetics&typeID=&sizeID.

Behavioral genetics is a field of behavioral science which attempts to summarize the separate contributions of genetic and environmental influences on a given phenotype. Frequently behavioral genetic researchers attempt to decompose this variance into three sources: (1) *heritability*, which describes the proportion of variance in an outcome that is thought to be explained by all genetic influences; (2) *shared environments*, which characterizes the environmental influences which make pairs of individuals more phenotypically similar; and (3) *unshared environments*, which characterizes the environmental influences which make pairs of individuals more phenotypically dissimilar. Behavioral genetics studies are frequently conducted using twin studies (which compares the phenotypic similarity of monozygotic twins, who are genetically identical, and dizygotic twins, who share 50% of their genes on average by descent) and adoption studies (which compares the phenotypic similarity of adopted sibling pairs to that of nonadopted members of their biological family).

When genetic information is available from subjects in a study, researchers can do two types of research. The first is called a *candidate gene* study in which individuals are classified into groups in which they are comparable to one another across segments of the human genome that are responsible for known physiological functions. These different groups are then compared with one another to see whether they are different with respect to some behavior like smoking, height, etc. There are many different statistical techniques for *candidate gene* studies, but using the correct method, researchers can conclude that the gene is actually responsible for differences in the trait and accounts for the similarity of family members who are much more likely to share the gene than two unrelated individuals. *Genome-wide association studies* (GWAS) incorporate data on a large number of SNPs (typically between 100 000 and 2 000 000 at this time) in order to identify loci associated with a phenotype of interest. Whereas the *candidate gene* method is a deductive exercise in which a specific hypothesis is tested, GWAS methods are entirely inductive and are much better characterized as a discovery science. In essence, GWAS models compare those with a specific illness (e.g., cancer) to those who do not have this illness (in which large efforts are made to provide the most meaningful comparisons) across each SNP in the human genome. Currently, genome-wide genotyping provide nearly 2.5 million SNPs. The strongest associations that emerge from this data mining exercise are then investigated to see whether they have any physiological pathway through which they might actually affect the trait of interest.

Additive Genetic and Environmental Effects

Sometimes both biological and environmental processes influence an outcome, but these influences are not interdependent. In other words, a given biological condition will have a certain influence on an outcome regardless of the environmental condition, and vice versa. Although this situation is not

traditionally grouped with gene–environment interplay, it is nonetheless an instance where considering biology and environmental influences jointly is potentially important. For instance, suppose that the odds of experiencing a myocardial infarction (heart attack) conforms to a threshold model, wherein a heart attack occurs when sufficient stress has been placed on the cardiovascular system from any source. In such an instance, one might suppose that any combination of genetic and environmental influences might combine non-interactively to produce the disease outcome in question.

To take an empirical example, consider the findings of Daw and Guo (2011) on the odds of an adolescent reporting contraceptive usage in their most recent sexual encounter. These researchers found that the odds of contraceptive nonuse were strongly linked to the dopamine transporter gene *DAT1*, the dopamine receptor gene *DRD2*, and the monoamine oxidase gene (*MAOA*). Furthermore, using multivariate logistic regression techniques, they found that these results held true when a wide range of social environmental and attitudinal variables that had previously been linked to contraceptive behavior were controlled. Finally, they found that these genetic and environmental influences on contraceptive behavior were noninteractive, although the genetic associations did vary somewhat by gender. In other words, environmental and attitudinal determinants of contraceptive behavior were independent from the genetic determinants. Recognizing that unprotected sex can occur as a function of both environmental *and* genetic influences was, however, an unprecedented contribution to social scientific understanding of this important outcome.

Gene–Environment Correlations

Gene–environment correlations (rGE) occur when genetic factors are associated with the causally important aspects of an environment for a given outcome. This can create the appearance of a genetic association with a phenotype where none exists – for instance, if gene G is correlated with environment E which is associated with phenotype P, a regression of P on G without a control for E will result in the appearance of an association of G with P. This is statistically identical to the more familiar problem of statistical confounding.

However, gene–environment correlations are also a substantively interesting social process. For instance, Price and Jaffee (2008) found that children whose parents have lower verbal abilities are reared in environments with more household disorganization, which is associated with children's intellectual development. In other words, children's verbal abilities resemble their parents' in part because of the association of genes linked with verbal ability with household disorganization as well as those children's inheritance of those same genes. This is known as a *passive gene–environment correlation*, in which environments which one did not select or evoke are correlated with one's genes and influence one's phenotypes.

Another form of gene–environment correlation occurs when one's genetically linked traits elicit different environmental influences on one's phenotype. This is known as an *evocative gene–environment correlation*. This type of rGE is rarely studied in humans, but one can conjure some hypothetical examples. Suppose, for instance, that one's physical attractiveness is partially genetically influenced, which appears to be the case. (For instance, in the National Longitudinal Study of Adolescent Health (Add Health), interviewers were asked to rate respondents' physical attractiveness on a 1–5 scale. The correlation of this measure among monozygotic twins is 0.620, and the correlation among dizygotic twins is 0.330. According to the standard twin model calculation, this indicates that interviewer-rated attractiveness is $2*(r_{MZ} - r_{DZ}) = 2(0.620 - 0.330) = 0.58$ heritable, a relatively high value.) Suppose further that one's physical attractiveness is positively associated with one's popularity, which also appears to be the case. (In Add Health, the correlation between one's interviewer-rated physical attractiveness and the number of others at one's school who nominate one as a friend is 0.158.)

Finally, suppose that one's self-esteem is positively associated with one's popularity, which also appears to be the case, albeit only moderately. (In Add Health, they ask how often, in the past week, the respondent felt that they 'were just as good as other people' on a 0–3 scale, which we take as a crude measure of self-esteem. This measure has a polychoric correlation of 0.059 with popularity.) In this case, one could argue that genetic influences on physical attractiveness have an evocative rGE relationship with self-esteem due to their correlation with popularity. Although this evidence does not prove that this is the case, it illustrates how this form of gene–environment interplay operates.

A final form of gene–environment correlation occurs when individuals select into different types of environments as a result of their genetic influences. This is known as an *active gene–environment correlation*. An example was identified by Cleveland et al. (2005), who found evidence for genetic associations with having friends who smoke and drink. Because this environment is associated with subsequent adoption of smoking and drinking behaviors, this is likely an example of an active rGE.

Gene–Environment Interactions

A *gene–environment interaction* describes a statistical relationship in which the effects of a gene G on a phenotype P depends on the value of an environment E. (It is equally correct to say that the environmental effect depends on the genotype.) For example, perhaps the most famous recent gene–environment interaction finding is that by Caspi et al. (2003), who found that the effects of stressful life events on depressive symptomology were conditional on an individual's genotype for the serotonin transporter gene *5-HTT*, such that those with more short alleles showed greater depressogenic effects. This is shown in **Figure 3** in which all individuals are susceptible to the effects of stress exposure on their mental health (e.g., all three lines have positive slopes) but the s/s group (e.g., those with two copies of the short allele) are the *most sensitive* to this same environmental influence. Similarly, the l/l group (e.g., those with two copies of the long allele) seems to be far more resilient after facing an increasing number of stressful life events. These findings help to explain

Figure 3 The effects of stressful life events on self-reported depression by genotype (Caspi et al., 2003). Results of multiple regression analyses estimating the association between number of stressful life events (between ages 21 and 26 years) and depression outcomes at age 26 as a function of 5-HTT genotype. Among the 146 s/s homozygotes, 43 (29%), 37 (25%), 28 (19%), 15 (10%), and 23 (16%) study members experienced zero, one, two, three, and four or more stressful events, respectively. Among the 435 s/l heterozygotes, 141 (32%), 101 (23%), 76 (17%), 49 (11%), and 68 (16%) experienced zero, one, two, three, and four or more stressful events. Among the 264 l/l homozygotes, 79 (29%), 73 (28%), 57 (21%), 26 (10%), and 29 (11%) experienced zero, one, two, three, and four or more stressful events. The main effect of 5-HTTLPR (i.e., an effect not conditional on other variables) was marginally significant ($b = -0.96$, SE $= 0.52$, $t = 1.86$, $P = .06$), the main effect of stressful life events was significant ($b = 1.75$, SE $= 0.23$, $t = 7.45$, $P < .001$), and the interaction between 5-HTTLPR and life events was in the predicted direction ($b = -0.89$, SE $= 0.37$, $t = 2.39$, $P = .02$). The interaction showed that the effect of life events on self-reports of depression symptoms was stronger among individuals carrying an s allele ($b = 2.52$, SE $= 0.66$, $t = 3.82$, $P < .001$ among s/s homozygotes, and $b = 1.71$, SE $= 0.34$, $t = 5.02$, $P < .001$ among s/l heterozygotes) than among l/l homozygotes ($b = 0.77$, SE $= 0.43$, $t = 1.79$, $P = .08$).

why some people may respond very differently to the same environmental signal.

Allele by Environment Interactions

However, this approach – in which the effect of a single environment is conditioned on one's genotype for a single gene – is but one of many that one can adopt when investigating gene–environment interactions. We call this approach the *allele by environment* strategy. To conduct such a study, one should identify a key environmental determinant of a dependent variable one wishes to investigate. Next, one should identify a gene that influences a hypothesized biological pathway influencing this outcome. Frequently genes involved in the reward and neurotransmitter pathways of the brain have been popular choices due to their obvious behavioral relevance and, recently, their common availability in social science datasets, but such investigations need not be restricted to these sorts of genes. Genes with documented main effects on the phenotype in question are often tempting targets for use in allele by environment studies, but theoretically these investigations need not be limited to these sorts of genes, either. For instance, variation in the *5HTT* gene has been linked to differential response to a range of environments for a variety of phenotypes (e.g., Caspi et al., 2003; Daw et al., 2013; Simons et al., 2011).

Heritability by Environment Interactions

An additional strategy for investigating gene–environment interactions adopts a behavioral genetic approach, modeling changes in the heritability of traits across different types of environments. We call this the *heritability by environment* approach. As briefly discussed above, heritability estimates are typically obtained by comparing the phenotypic similarity of pairs of individuals with different known genetic relationships. For instance, monozygotic (MZ) twins are genetically identical, whereas dizygotic (DZ) twins share about half of their genes on average by common descent, as do full siblings and parent–child pairs. (However, parent–child pairs show far less variance in the proportion of shared alleles than do full sibling pairs.) Similarly, half siblings, grandparent–grandchild, and aunt/uncle–niece/nephew pairs share about 25% of their genome by common descent, and cousins share about 12.5%. Using family-based data and this type of basic genetic information, one can calculate the heritability as the proportion of variance in a phenotype explained by genetic similarity between biological family pairs. Using extensions of this basic family-based model, one can also estimate the degree to which this estimate varies systematically with an environmental characteristic.

A recent example of this approach was published by Boardman (2009), who used a multilevel twin and sibling model to show that the heritability of smoking was lower in states with high cigarette taxes, and higher in states with lower cigarette taxes. This paper further found that heritability of cigarette smoking is higher in states with lower overall smoking rates. An additional example was documented by Turkheimer et al. (2003), who investigated whether the heritability of intelligent quotient (IQ) varies by the poverty rate of the respondents' neighborhood. This investigation showed that the heritability of IQ increased dramatically, and the shared environmental component decreased dramatically, with increasing neighborhood socioeconomic status. Findings such as these emphasize that heritability estimates are frequently contingent on the environmental context.

Genome-Wide Gene–Environment Interactions

Finally, an emergent approach to the study of gene–environment interactions has been facilitated by the declining costs of genotyping human DNA. Using GWAS datasets, one may now estimate *genome-wide gene–environment interactions* (GWGEI) using a phenotype and environment of interest without the need to select the gene of interest a priori (Cornelis et al., 2012; Mukherjee et al., 2012; Thomas et al., 2012). With available methodologies, this can be done using at least two approaches. First, as with standard GWAS, one can estimate the main effect and interaction of each SNP and a selected environment, and then perform Bonferroni adjustments on the resultant interactions to determine which interactions are statistically significant above the level expected by chance. One could theoretically perform such an analysis for every combination of genes and environments available in a dataset,

but this has not thus far been attempted in any published article to our knowledge. Second, a recently developed method/software called Genome-wide Complex Trait Analysis (GCTA) permits calculation of heritability estimates using GWAS data instead of pairs of individuals with known genetic relationships (Yang et al., 2010). One can also extend this method to estimate interactions between this molecular genetic heritability estimate and an environment of interest (Boardman et al., forthcoming). We will refer to this as the GCTAxE method. Although these are new approaches to the study of gene–environment interactions, these and related methods are very likely to be increasingly pursued given the increasing availability of genome-wide data in popular social science datasets such as the Health and Retirement Study and the National Longitudinal Study of Adolescent Health.

Theoretical Approaches to Heritability–Environment Interactions

When investigating gene–environment interactions, the functional form of the interaction is often of substantive theoretical interest. For instance, a heritability by environment interaction is more than simply a statistical novelty – it is a guide to identifying the type of environments in which biology can 'shine through' (Raine, 2002) (or cannot). When heritability is high, genetic influences hold relative sway; when heritability is low, social environments dominate. Frequently, the types of environments in which heritability are higher and lower is relatively predictable. Accordingly, a set of conceptual models have been characterized to describe the patterns observed. These are illustrated for the reader's reference in **Figure 4**.

The *social distinction* model hypothesizes that heritability estimates will be highest in the most advantageous environments and lowest in the most disadvantaged environments, with approximately linear change in between. In other words, the primary effect of the social environment is to preclude genetic influence. Many authors have argued that this is likely to be the case (Boardman et al., forthcoming; Nielsen, 2006) at least in certain situations. In contrast, the *social push* model (Raine, 2002) makes the key distinction that between middle-range and extreme environments, positing that heritability estimates will be highest in the former and lowest in the latter. The underlying theory argues that in extreme social environments, the environment is a leveling force, leading to lesser overall phenotypic variation. However, within normal social environments, genetics continue to exert significant influence. Boardman et al. (2012b) show that the heritability of body mass index (BMI) is the highest in schools with average BMI levels ($h^2 = 0.87$) and substantially lower in schools with a very low average BMI ($h^2 = 0.74$) and those with very high average BMI ($h^2 = 0.73$).

The most frequently identified empirical pattern of heritability by environment interactions is characterized by the *social control* model (Shanahan and Hofer, 2005), which predicts that heritability will be inversely related to environmental advantage, in the opposite direction of the predictions of the social distinction model. The theoretical conjecture underlying this empirical pattern is that more advantageous social environments also tend to have norms and laws which restrict individual actions for the phenotype in question. As an example of this model, consider the work of Boardman (2009) who shows that genetic influence on regular smoking are significantly reduced in states that have the highest rates of taxation on cigarettes. Finally, the *differential susceptibility* predicts the opposite patterns of those found in the social push model, with high heritability estimates in environmental extremes and comparatively low ones in middle-range environments. One likely possible explanation for such a pattern would be that there is greater overall phenotypic variation in middle-advantage environments compared with less- and more-advantaged environments. If this were the case and molecular genetic effects remained constant, heritability estimates would be inflated in the environmental extremes and deflated in the middle-range (since heritability is the ratio of variance explained by genetics and overall variance).

Theoretical Approaches to Allele–Environment Interactions

Allele–environment interactions also carry theoretical implications for social scientists, though perhaps less sweeping ones than those for the heritability–environment interactions. Perhaps the most important implication of these models is that individuals exhibit differential phenotypic responses to common environmental determinants. In other words, persons

Figure 4 Heritability by environment conceptual models.

with one genotype may exhibit strong responses to environmental stimuli or conditions, whereas those with other genotypes may show a weaker response, no response, or even a response in the opposite direction. Such findings, which are relatively common now, remind us that frequently the environmental effects that social scientists typically document are only averages. (The same can be said for genetic main effects documented by biologists.)

These interactions come in a variety of functional forms, which are graphically depicted in **Figure 5**, and we discuss with reference to health outcomes (the most commonly studied phenotypes in allele–environment interaction research). The most common theoretical model in the allele–environment interaction literature is the *diathesis-stress* model, also known as the *social trigger* model (Ellis et al., 2011; Shanahan and Hofer, 2005). The intuition that underlies this model is that unhealthy environments increase the odds of poor health outcomes – but not for everyone. Instead, those with more 'risk' alleles at the locus in question bear the brunt of the insalubrious effects of these environments, while those with fewer risk alleles show little change in their expectation of this outcome. The Caspi et al. (2003) paper discussed earlier is the most widely cited example of this model.

However, the *differential susceptibility* model has become increasingly common in recent years of research. This model predicts a statistically significant 'crossover' in expected odds of a poor health outcome, such that persons with one type of genotype – more 'sensitivity alleles' – will be showing a far steeper relationship between the environment and the phenotype than those with fewer such alleles, resulting in higher odds of poor health outcomes in poor environments and lower odds thereof in favorable environments. This pattern sometimes characterizes the population as consisting of two groups – 'dandelions,' which can grow in any environment, and 'orchids,' which require very beneficial environments to grow at all but flourish beautifully in the right one (Boyce and Ellis, 2005). For instance, Simons et al. (2011) finds that persons with more sensitivity alleles at the *5HTT* and *DRD4* genes exhibit higher antisocial behavior in adverse environments, and lower antisocial behavior in beneficial ones, than their less genetically sensitive counterparts. Similarly, recent work by Daw et al. (2013) extends this model to cigarette smoking and alcohol use, finding that individuals with more *5HTT* sensitivity alleles smoke and drink more in high-smoking and high-drinking schools, respectively, but show the opposite pattern in low-smoking and low-drinking schools.

A less common theoretical model of allele–environment interaction (at least in social science research) is what we term the *alternative optima* model. This is the implicit model underlying the pursuit of personalized medicine, or the (thus far unrealized) notion that one can use patients' genetic codes to determine the optimal genome-specific therapy for their ailments. If one thinks of therapeutic interventions as the environment in question, then the hypothesis underlying this medical research program is that persons with one genotype

Figure 5 Conceptual models of allele by environment interactions.

will have optimal outcomes under one treatment whereas others with different genotypes will best thrive in a categorically different environment. Note that, unlike other allele–environment models, this does not imply a rank-ordering of environments. Rather, the environments are qualitatively different.

Finally, the *social push/distinction* model of allele–environment interaction argues that a particular genotype will be associated with a health outcome in the most advantageous environments, but not otherwise. Boardman et al. (2012a) demonstrate support for this perspective in which they examine the link between a gene responsible for producing a protein that, when combined with fats, created lipoproteins which move cholesterol around the bloodstream. An allele in this gene (e4) is linked to Alzheimer's disease and cognitive functioning among older adults. These researchers show that the e4 allele is only linked to cognitive functioning among adults from the *most stable, safe, and organized neighborhoods*. This is because there is too much environmental variation in the poorest and most disorganized neighborhoods in Chicago such that genetic differences cannot differentiate between people in these communities. This is shown graphically in **Figure 6** in which each dot corresponds to the estimated effect of the risky e4 allele in the ApoE gene for each of the neighborhoods in this study. While there is variation about this general theme, on average, the effect of the gene is significantly reduced among residents who live in the most disadvantaged neighborhoods. In these neighborhoods, the environment (the social environment) is 'pushing' the phenotype rather than genes.

Figure 6 Neighborhood variation in the effect of ApoE genotype and cognitive functioning among older adults. *Note*: Values on the horizontal axis describe the level of social disorder that is present across the 20 neighborhoods in the Chicago Health and Aging Project. The values on the vertical axis denote the absolute value of the effect of the ApoE4 allele on changes in cognitive function from the baseline to the follow-up for each of the 20 neighborhoods. The lines correspond to the mean values for the vertical and horizontal axes.

Limitations of Gene–Environment Interplay Research

We hope that by now the promise of gene–environment interaction research is clear: at its best, it holds the potential to integrate our understandings of humans as both biological and social beings. In practice, this line of research is far from fulfilling this grand promise, and progress toward this goal has not proceeded monotonically.

A number of obstacles impede this goal, of which we emphasize a few. One primary limitation is that, amidst the spiraling numbers of findings on gene–environment interplay that have been reported in academic journals and the press, little in the way of a coherent theoretical framework has emerged to aid in understanding this huge agglomeration of findings. Instead, progress in this field has tended to come primarily in the form of methodological and data-collection advances. Twin and adoption studies have led to expanded family-based methodologies, *candidate gene* studies have led to GWAS (and, soon, full-genome-sequencing of more than 3 billion base pairs), and allele–environment interactions have led to GWGEI and GCTAxE. Yet as increasingly sophisticated techniques for characterizing genotypic variation have flooded the research community with data and findings, little progress has been made in aiding the interested party in predicting the sorts of environments in which one will see higher or lower genetic influence (or complementarily, higher or lower environmental influence). It is possible that there are no robust patterns across phenotypes, genotypes, and environments. At present the best one can hope to do is characterize one's isolated findings in terms of the conceptual models described above. And even with this humbler goal, obstacles remain. Crucially, it is often quite difficult to distinguish between these alternative models outside of conceptual charts.

Another key limitation for this line of research is that gene–environment interplay findings are frequently not replicated. The most highly cited allele–environment interaction, by Caspi et al. (2003), is an interesting case study. This is the article that launched a 1000 replications. Yet still no consensus has been reached on the generalization of this finding (Risch et al., 2009). Progress in understanding gene–environment interplay depends heavily on the ability to test the reproducibility of these findings, since enough researchers studying a given interaction using different datasets and modeling techniques will naturally produce a certain set of false positives (Duncan and Keller, 2011). Furthermore, gene–environment interaction research often has enormous power requirements (Duncan and Keller, 2011), and funds are limited to collect survey and genotypic data on samples of the requisite size. Accordingly, the ability of the scientific community to adequately test the validity of these types of findings is hamstrung by the fact that many researchers in this field work with the same set of large datasets incorporating genotypic data (the National Longitudinal Study of Adolescent Health, the Framingham Heart Study, the Wisconsin Longitudinal Study, the National Health and Nutrition Examination Study, and the Health and Retirement Study).

Finally, research on gene–environment interplay faces a particular challenge known as *population stratification* (e.g., Price et al., 2006). This is a form of confounding for the association between a genotype and a phenotype (or a gene–

environment correlation). Simply put, due to historical patterns of migration, genetic bottlenecks, and *de novo* mutations, some genotypes are more common in populations hailing from certain geographic regions than others. If being a descendant from a group where such an allele is more common is associated with a phenotype compared with descent from a group in which such an allele is less common, a spurious association may be observed if membership in these groups is not controlled for. Fortunately, numerous techniques exist to address this problem: principal components analysis using GWAS data (Price et al., 2006), controls for ancestrally-informative markers (Nassir et al., 2009), and using within-family estimators such as fixed effects regression (Daw et al., 2013), and most academic journals familiar with this research would now require that these concerns be addressed before publishing research reports using gene–environment interplay.

Of course, many research subfields discussed in this volume face challenges such as these. Population stratification is simply the geneticists' term for confounding, with which nearly all social and behavioral scientists should be familiar. All quantitative subfields in the social and behavioral sciences wish they had more and larger datasets with better measures with which to maximize the power of their analyses and likelihood of reproducing 'real' associations. And, while the theoretical stagnation of the gene–environment interplay field is concerning, the rapid rate of technological and methodological advances seen in this field is the envy of most. We hope that the theory will catch up soon.

Conclusion

Gene–environment interplay research addresses the ways in which genetic and environmental determinants of social and behavioral outcomes are interdependent. These primarily include additive genetic and environmental effects, gene–environment correlation, and gene–environment interactions. Different conceptual models of each of these forms of gene–environment interplay were described. The limitations and major obstacles to progress in this field were also noted. While gene–environment interplay research holds great promise and has seen rapid advancement, it also faces a number of substantial obstacles that impede its ability to achieve that promise. Future research should seek to address these limitations while expanding the theoretical, technological, and empirical boundaries of the field as it stands today.

Abstract

Generalizability theory (G theory) provides a framework for conceptualizing, investigating, and designing reliable observations. It was originally introduced by Cronbach and colleagues in response to limitations of the popular true-score model of classical reliability theory. G theory reinterprets classical reliability theory as a theory regarding the adequacy with which one can generalize from a sample of observations to a universe of observations from which it was randomly sampled. Because observations may conceivably be generalized to many different universes, observations may vary in how reliably they permit inferences about these universes and, therefore, be associated with different reliability coefficients. G theory also shows how the traditional distinction between reliability and validity can be overcome to design dependable observations. In G theory, a universe, its facets, and the conditions for admissible observations are defined through careful construct explication, the traditional domain of validity theory. The use of the terms 'dependability' and 'generalizability' instead of 'reliability' reflects the interest in unifying reliability and validity. How to go about designing and investigating dependable measures is the subject of G theory.

Overview

Generalizability theory (G theory) provides a framework for conceptualizing, investigating, and designing reliable observations. It was originally introduced by Cronbach et al. (1963, 1972) in response to limitations of the still popular true-score model of classical reliability theory (Spearman, 1904, 1910). Classical reliability theory centers on the notion that each observation or test score has a single true score, belongs to one family of parallel observations, and yields a single reliability coefficient (Nunnally and Bernstein, 1994). While this model may be reasonable for carefully equated parallel forms of tests, it is overly restrictive and often unrealistic in situations where, for instance, raters differ in the central tendency and variance, observations depend on the context in which they occur, and constructs are patently heterogeneous. Several writers argued in the 1950s and 1960s that the same observation could conceivably belong to more than one set of parallel tests and thus have more than one reliability coefficient (Cronbach et al., 1963; Guttman, 1953; Tryon, 1957). The fact that the internal consistency reliability estimate of a multidimensional measure tends to be low even when test–retest and alternate forms reliability estimates are high illustrates the contradictions and limitations of the classical reliability model.

It was Cronbach's vision to reinterpret classical reliability theory as a theory regarding the adequacy with which one can generalize from a sample of observations to a universe of observations from which it was randomly sampled. G theory acknowledges that the reliability of an observation depends on the universe about which the investigator wants to draw inferences. Because a particular measure may conceivably be generalized to many different universes, a measure may vary in how reliably it permits inferences about these universes and, therefore, be associated with different reliability coefficients. G theory explicitly requires investigators to specify a universe of conditions over which they wish to generalize. The extent to which different conditions are associated with different observations has implications for designing dependable observations.

G theory not only reinterprets classical reliability theory but also shows how the traditional distinction between reliability and validity can be overcome to design dependable observations. Traditionally, construct validity is concerned with drawing inferences about a latent construct based on observable measures, whereas reliability is concerned with drawing inferences about a true score from observations across parallel measures. In G theory, a universe, its facets, and the conditions for admissible observations are defined through careful construct explication, the traditional domain of validity theory. G theory defines observations as dependable if they permit accurate inferences about the latent construct (i.e., the universe of admissible observations) they are meant to represent. In doing so, G theory blurs the traditional distinction between reliability and validity. The use of the terms 'dependability' and 'generalizability' instead of 'reliability' reflects the interest in unifying reliability and validity. How to go about designing and investigating dependable measures is the subject of G theory.

Key Concepts

The Decision Maker

Measurements are designed with applications in mind, and their quality has to be examined in the context of their application. This context is symbolized by the 'decision maker' who is interested in measuring a particular construct in a particular population of persons, under a particular universe of conditions, and with particular types of decisions in mind.

Types of Decisions

The types of decisions for which a measurement instrument is to be used have to be known before an instrument that yields dependable observations can be designed. Two major types of decisions have to be distinguished. The first concerns decisions that rely on the relative ranking of individuals. Accepting the three top-scoring applicants for a position is an example of a decision relying on the relative interpretation of scores. Measurements that emphasize the interpretation of the relative differences between scores are the domain of classical test theory with its traditional focus on interindividual differences.

The second major type of decisions is based on the interpretation of the absolute level of scores. Mastery tests in education provide an example of a decision based on the absolute interpretation of a score. Similarly, preestablished admissions standards for college (e.g., minimum SAT score) or pass/fail standards on job selection tests rely on the interpretation of absolute score levels.

The Universe of Admissible Observations

A measurement consists of a sample from the universe of admissible observations. What defines a universe for a particular measurement is based on what the decision maker is willing to treat as interchangeable for the purposes of making a decision. Thus, a universe may consist of interchangeable three-letter syllables, symptoms of depression, or interviewers if the decision maker is willing to treat as interchangeable three-letter syllables, depressive symptoms, and interviewers. A universe may consist of interchangeable time points for urine collection, survey questions about voting behavior, or situations for observing altruistic behaviors if the decision maker considers those aspects of measurement as interchangeable.

Estimating a Person's Universe Score

Given a particular universe of admissible observations, a person's universe score (μ_p) can be defined as the average score based on all admissible observations (X_{pi}) of the universe of interest. The purpose of a measurement is to accurately estimate this universe score ($\hat{\mu}_p$) based on a sample of observations.

The degree to which a measurement is generalizable depends on how accurately the measurement permits us to estimate the universe score. The accuracy of an observation is captured in the variance associated with the different presumably interchangeable observations. The extent to which different items, different observers, or different measurement occasions yield different observations determines how dependable a single specific observation is. In other words, if different items, observers, etc., yield similar observations, a single measurement may allow accurate inferences about the universe of observations. If different items, observers, occasions, etc., yield dissimilar observations, inferences about the underlying universe based on a single observation may be questionable.

The Universe and Its Facets

Universes can be simple or complex, homogenous or heterogeneous, and small or large depending on the construct of interest and the decision maker's interest in investigating different aspects or facets of generalizability. The terms 'facets' and 'conditions' are analogous to 'factors' and 'levels' in the literature on experimental design. A universe of observations is said to consist of one facet if the generalizability of observations regarding one source of variation in the universe, say arithmetic questions of varying difficulty, is at stake. For instance, a particular arithmetic test includes a sample of items, covering different addition, subtraction, multiplication, and division problems of one- and two-digit numbers. The decision maker is interested in general arithmetic achievement and is indifferent to the particular questions on the test. In the one-facet design, one is interested in estimating the universe score of each person based on the sample of items included in the test.

A universe is said to have two (or more) facets if the generalizability of observations regarding two (or more) sources of variation in the universe, say items and occasions, is at stake. For instance, to the extent that arithmetic achievement depends on the difficulty of the items and the test occasions (e.g., beginning or end of school year), the generalizability of a particular measure taken early in the school year on a sample of difficult items may be compromised.

Generalizability Studies

Generalizability studies (G studies) are conducted to investigate the relationship between an observed score and a universe score. They are designed to provide information regarding the sources of variability (i.e., facets of the universe) that influence the generalizability of observations. Because the dependability of a measure rests on its purpose (and thus the universe of admissible observations it is meant to represent), different G studies may be needed depending on the proposed application of the measure. Alternatively, a single G study has to anticipate the multiple uses of a measurement to provide as much information as possible about potentially important sources of variation.

In the above example, arithmetic items varying in difficulty is an obvious choice of a facet to be examined in a G study. In addition, decision makers may be interested in whether measures taken at different occasions, based on different response formats, based on different presentation modes, etc., yield different observations. To examine these issues, a universe has to be defined more broadly to include items of different difficulties, response formats, presentation modes, and taken at different occasions. Having defined such a multifaceted universe, a G study has to be designed to investigate the contributions of these facets and their interactions to the overall variance in observations.

Decision Studies

G studies are designed to assess the dependability of a particular measurement technique. In contrast, decision studies (D studies) are designed to gather data based on which decisions about individuals are made. D studies rely on the evidence generated by G studies to design dependable measures for a particular decision and a particular set of facets about which a decision maker would like to generalize. The goal is to design

a measure that samples sufficient numbers of instances from different facets of a universe of observations to yield a sufficiently dependable estimate of the universe score that the measure is meant to represent.

Illustrative Generalizability Design

Generalizability Design

For illustration, the statistical models and analyses for a one-facet G study will be presented. This most simple generalizability design requires making observations (X_{pi}) on individual subjects (1, 2, …, p,…, n_p) under different conditions of a facet (1, 2, …, i, …, n_i), where subjects and conditions represent random samples from their respective universes. In a one-facet design, the universe of admissible observations consists of observations that differ with respect to one characteristic, say item difficulty. The generalizability question is, how dependable are observations made under different conditions to draw inferences about the universe consisting of all conditions?

The Statistical Model

A one-factorial analysis of variance (ANOVA) model can be used to describe how the observed score of person p under condition i can be partitioned into a grand mean (μ), an effect for each person (π_p), an effect for each item (α_i), and a residual (ε_{pi}).

$$X_{pi} = \mu + \pi_p + \alpha_i + \varepsilon_{pi} \quad [1]$$

In eqn [1], the grand mean (μ) is a constant value for all persons, positioning the score for all persons on the particular scale of measurement. The person effect (π_p) describes the difference between a person's universe score and the grand mean ($\mu_p - \mu$), indicating interindividual differences in universe scores. The item effect (α_i) indicates the difference between an item's difficulty and the average item difficulty ($\mu_i - \mu$), reflecting the variability associated with the facet of error being investigated. The residual combines the influence of the person-by-item interaction, systematic sources of error other than items, and random events.

According to this model, specific observations X_{pi} vary due to differences between persons (i.e., person effects), differences between items (i.e., item effect), and other unaccounted for sources (i.e., residual). Accordingly (see eqn [2]), the variance of a set of observed scores ($\sigma^2_{X_{pi}}$) can be partitioned into components due to persons (σ^2_p), items (σ^2_i), and the residual (σ^2_ε). The residual combines two sources of variance that cannot be distinguished from each other in this model. They are the person-by-item interaction (i.e., items vary in difficulty between persons; persons vary in their ranking on different items) and chance fluctuations in scores.

$$\sigma^2_{X_{pi}} = \sigma^2_p + \sigma^2_i + \sigma^2_{pi,\varepsilon} \quad [2]$$

Generalizability Study: Estimation of Variance Components

To estimate these variance components, a G study has to be conducted in which data are collected on a representative sample of persons and items. Variance estimates can be derived from the mean squares (MS) reported as part of the standard ANOVA printout of statistical analysis programs (see eqns [3]–[5]), in which persons are identified as between-subjects factor and items as within-subjects factor.

$$\hat{\sigma}^2_{pi,\varepsilon} = \mathrm{MS}_{\mathrm{residual}} \quad [3]$$

$$\hat{\sigma}^2_p = (\mathrm{MS}_p - \mathrm{MS}_{\mathrm{residual}})/n_i \quad [4]$$

$$\hat{\sigma}^2_i = (\mathrm{MS}_i - \mathrm{MS}_{\mathrm{residual}})/n_p \quad [5]$$

A Numerical Example

Table 1 shows findings from a G study in which 1275 persons rated the frequency with which they experienced 20 depressive symptoms. This data set may be downloaded at http://x.doi.org/10/1016/B978-0-08-097-86-8.44027-4. The table presents the numerical estimates and the percentage of total variance accounted for by persons, items, and the residual.

Interpretation of Variance Components

Variance components reveal information about how different sources of variability affect the response to a single item. For instance, the variance component associated with items in the above example is 0.0195, accounting for 5.1% of the total variance. This variance component indicates how much the mean of any one randomly selected item is expected to vary from the mean of all items in the universe. Clearly, the magnitude of a variance component depends on how the items were scored (e.g., 1, 2, 3, 4 or 10, 20, 30, 40). In this example, items were scored 1, 2, 3, 4, where 1 indicates the absence of depressive symptoms and 4 indicates the symptoms were present all the time. The average item mean (i.e., estimate of the mean of all items in the universe, $\hat{\mu}_p$) was 1.36, indicating that most respondents reported the absence of depressive symptoms. Taking the square root of the variance component $\sqrt{0.0195}$ yields a standard deviation of 0.1396. Because 95% of item means will fall within 1.96 standard deviations ($1.96 * \pm 0.1396 = \pm 0.2736$) of the overall mean, we would expect 95% of item means to fall between 1.09 and 1.63 (i.e., 95% confidence interval (CI) = [1.09; 1.63]). Given that the possible range of item scores is 1–4, the expected range indicates that the item means in the universe of admissible items will mostly vary between 1 and 2.

The variance component for persons is 0.0687 or approximately 17.9% of the total variance. This variance component estimates the universe score variance, that is, the between-person variability in the average item scores across all the

Table 1 ANOVA MS and estimates of variance components for a one-facet G study

Source of variation	*MS*	*Numerical estimate*	*Percentage of total variance*
Persons (p)	1.6701	$\hat{\sigma}^2_p = 0.0687$	17.9
Items (i)	25.1355	$\hat{\sigma}^2_i = 0.0195$	5.1
Residual (pi, ε)	0.2955	$\hat{\sigma}^2_{pi,\varepsilon} = 0.2955$	77
Total	0.3827	$\hat{\sigma}^2_{X_{pi}} = 0.3842$	100

admissible items of the universe. Based on the variance component, the standard deviation is 0.2621, indicating that 95% of universe scores are expected to fall between ±0.5137 of the grand mean (95% CI = [0.85; 1.87]).

Similar to the reliability coefficient in classical measurement theory, G theory yields a coefficient of generalizability (ρ^2) based on a particular generalizability design. It is defined as the ratio of universe-score and observed-score variances. In this example, the G coefficient for a single item is $\hat{\rho}^2 = \hat{\sigma}_p^2/\hat{\sigma}_{X_{pi}}^2 = 0.1788$. Similarly, intraclass correlation coefficients can be determined. For one item, it is $\alpha_{(1)} = (\mathrm{MS}_p - \mathrm{MS}_{\mathrm{res}})/(\mathrm{MS}_p + (n_i - 1)\mathrm{MS}_{\mathrm{res}}) = 0.1887$, and for the set of 20 items is $\alpha_{(20)} = (\mathrm{MS}_p - \mathrm{MS}_{\mathrm{res}})/\mathrm{MS}_p = 0.8231$. The latter is also known as the Cronbach α coefficient or KR20 formula.

By far the largest variance component is associated with the residual (i.e., 0.2955), accounting for approximately 77% of the total variance. This suggests that there are important sources of variance not accounted for by differences between persons or differences in item difficulties (i.e., item means). Because the residual consists of the item-by-person interaction, this variance component reflects the fact that subjects indicate somewhat different levels of depressive symptoms depending on which item they are responding to. Based on the variance component, the standard deviation is 0.5436, indicating that the response to a specific item is expected to fall within ±1.07 of a person's universe score in 95% of observations.

In summary, the results show that responses to a single item are mostly influenced by measurement error. Information about interindividual differences make up only 17.9% of the total variance, and information about differences in test items make up only 5.1% of the total variance in item responses. Clearly, a single test item is of little use in estimating a person's universe score; that is, a single item provides little foundation for generalizing to a person's universe score. Consequently, D studies must sample many items to achieve more dependable estimates. Exactly how many items is the subject of D studies.

Decision Study: Designing Generalizable Observations for Decisions

To conduct a D study, the relevant universe of observations and its facets must have been investigated in the G study. The type of decisions to be made have to be known, and the accuracy necessary to make the decisions has to specified. With this information at hand, the number of items from each facet of the universe can be determined such that dependable inferences can be drawn about the entire universe of observations at stake.

For instance, the decision maker in the previous example may want to design a measure that yields a 95% margin of error of ±0.20 for the estimate of a person's universe score. That is, the decision maker wants to be 95% confident that a person's universe score is within ±0.20 of the observed score. Based on this 95% margin of error (i.e., $0.20 = 1.96 * \sigma^2_{\mathrm{error}}$), the error variance of the universe score can be determined: $\sigma^2_{\mathrm{error}} = (0.20/1.96)^2 = 0.0104$.

For decisions based on the relative ranking of scores, the required number of items is

$$n_i' = \frac{\sigma^2_{pi,e}}{\sigma^2_{\mathrm{error|relative}}} \qquad [6]$$

For decision based on the absolute ranking of scores, the required number of items is

$$n_i' = \frac{\sigma_i^2 + \sigma^2_{pi,e}}{\sigma^2_{\mathrm{error|absolute}}} \qquad [7]$$

Thus, for relative decisions, we need to sample $n_i' = 0.2955/0.0104 = 28.41$ or 29 items. In addition, for absolute decisions, we need to sample $n_i' = (0.0195 + 0.2955)/0.0104 = 30.29$ or 31 items. In this example, very little variance is contributed by differences between items in their difficulties (i.e., σ_i^2), indicating that regardless of which items are sampled, similar absolute scores will be obtained. Consequently, only two additional items have to be sampled to yield equally dependable estimates of universe scores for relative and absolute decisions.

Extensions

The principles presented for a simple generalizability scenario can be extended to more complex designs consisting of two or more factors, which may be random or fixed, and which may be crossed or nested. The interested reader is referred to the works by Cronbach et al. (1972), Shavelson and Webb (1991), and Brennan (2001a). G theory can also be applied to the analysis of score profiles, composites, and difference scores, and extensions have been developed to estimate variance components via maximum likelihood, Bayesian, and covariance structure methods and for studying the dependability of any facet of observation. The interested reader is referred to the work by Brennan (2011), Gao and Harris (2012), Marcoulides (1996, 1999), Shavelson et al. (1989), Shavelson and Webb (2006), Wittmann (1988), and Webb et al. (1983).

Software

More than 40 years after its introduction, none of the major software packages for statistical analyses in the behavioral sciences have integrated dedicated G or D study analyses as part of their basic data analytic procedures, although most software packages provide estimates of α and intraclass coefficients as part of their reliability analyses. This is likely to have impeded the more widespread adoption of G and D studies in the behavioral sciences. The development of user-friendly programs to perform generalizability analysis should broaden the application of G and D studies. One such program developed principally for generalizability analysis is Generalized analysis of variance (GENOVA). Although originally developed in the early 1980s (Crick and Brennan, 1983), it has since been updated to a suite of computer programs consisting of GENOVA to evaluate univariate balanced designs without missing data, urGENOVA to evaluate unbalanced random effects designs, and mGENOVA to evaluate univariate and multivariate designs (Brennan, 2001b,c). EDUG (Cardinet et al., 2009) is another software package designed to perform generalizability analyses that promises ease of use. Readers are referred to Clauser's (2008) review for a comparison of the GENOVA and EDUG programs. Two kinds of user-written G theory programs were created for both SPSS and SAS. The SPSS and SAS G1 programs are reported to be easier to use but more

restricted in the kinds of permissible research designs than the G2 program. One such restriction is that missing values are not permitted with the G1 programs. Readers are referred to Mushquash and O'Connor (2006) for a comparison of the SPSS and SAS generalizability analysis programs.

Generalization: Conceptions in the Social Sciences

Thomas D Cook, Northwestern University, Evanston, IL, USA

This article is reproduced from the previous edition, volume 9, pp. 6037–6043, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

A major goal in the behavioral and social sciences is to offer conclusions that are valid for observed particulars extensive to abstract entities. Four different approaches to generalization are considered in this article. The first describes random sampling with its advantages and limitations. The second considers purposive selection in contrast to randomization. The third covers the possibility of generalizing causal statements and its connection to meta-analysis. And the last refers to extrapolation from a sample to nonsampled entities. This article concludes by arguing that random sampling, though limited, is the best formal method for generalization.

This article examines how social scientists go about probing the generality of causal connections. It distinguishes between on the one hand methods for generalizing to populations of persons and settings and for generalizing to target cause and effect constructs as and, on the other methods for generalizing across different person, setting, cause, and effect constructs. Random sampling is discussed as the best warranted method for generalizing, but its reach for probing the generality of causal connections is unfortunately limited. Methods used for generalizing to construct validity of causes and effects are less well-warranted and more cumbersome, but apply to persons and settings as well as to causes and effects. The generalizing across entities depends on stratification methods that can be used in individual studies. But they are most productively used when synthesizing across multiple studies of the same apparent question, as with meta-analysis. However, the most esteemed method for generalizing causal relationships is by identifying the mediating processes that explain why a cause and effect are related so that these same processes can be instantiated in novel circumstances that have never been examined before. So, causal explanation also helps describe the boundary conditions determining variation in the direction and size of a given causal relationship.

All social scientists use observed particulars to draw conclusions about abstract entities. In measurement theory, the argument that 'IQ is what an IQ test measures' is discredited, and informed debates take place to interpret what the observed scores mean in general language. Some qualitative researchers are also reluctant to generalize beyond observables, but their language is replete with summarizing statements and they invite readers to construct theoretical meanings beyond the descriptions offered. In laboratory research, scientists often study local student samples, not to construct theories about them or about students in general, but to make inferences about humans. Some laboratory researchers use animals to substitute for humans, and their case for cross-species generalization has to depend on arguments – e.g., that cats and humans share the anatomical and physiological attributes central for understanding whatever aspect of vision is under study. This article describes and evaluates many of the procedures for generalization that social scientists actually use.

Cronbach (1982) has perhaps the most comprehensive framework for understanding generalization. We use his theory, though slightly modifying it. He claims that social scientists typically draw conclusions about four not completely independent entities – human populations, physical settings, causes, and observables (including effects and moderators of cause–effect relationships). Time, understood as historical period, might also be added. Cronbach further contends that scientists work with samples, instances, cases, exemplars, or particulars (terms he uses almost interchangeably), and that these represent study-specific populations, categories, entities, universes, classes, constructs, or categories (terms he also uses interchangeably). A major task of all scientists is to identify the class a given set of lower-order instances represents.

Cronbach also understands generalization in terms of inferences about classes that the sampling specifics manifestly do not represent. Such knowledge transfer is particularly salient, for instance, when animals are studied as proxies for humans or when laboratories substitute for other social settings. But transfer is also involved when research on American senior citizens, say, is used to extrapolate to Americans in midlife or to seniors in Western Europe; or when findings about factories are extrapolated to schools on grounds that both are complex organizations. Extrapolation also pertains to causes and effects, as when studies of health care subsidies are applied to housing subsidies, or when a finding about a subsidy's effect on hospital utilization is applied to effects on mental health. Cronbach believes that methods are needed both for justifying inferences from particulars to generals (as from samples to populations or from measures to constructs) and for justifying extrapolations beyond the categories studied.

His schema also includes subcategories – e.g., the racial groups within some human population or the components constituting a construct-like stress. Researchers routinely partition data both to test a relationship's stability across the subcategories examined and to identify the conditions under which it varies. The more heterogeneous the subpopulations are over which a relationship holds, the greater its generality is usually assumed to be. In addition, the more specifically identified are the boundary conditionals limiting a relationship, the better its generality is understood. Campbell's external validity (Campbell, 1957) also emphasizes generalization across entities, but without restricting it to subtypes. For him, a relationship found among Austrians should be examined not just by partitioning Austrians into regional or generational

subgroups, but also by examining the same relationship across other nations. Findings that dependably replicate across very different circumstances are the foundation of all general science.

Using the Cronbach framework, we structure this exposition into four parts: (1) methods based on formal sampling theory, as they are and are not used for generalizing to clearly designated universes of people, settings, times, causes, and effects; (2) purposive sampling methods, especially as they are used in validating constructs; (3) methods for assessing the range of circumstances over which a causal connection holds; and (4) methods for extrapolating knowledge to entities with different characteristics from those on which the knowledge was originally established.

This phrasing acknowledges that many social scientists use universe (and population) differently from construct, though the later Cronbach tends to use them almost interchangeably. In statistics, populations are ostensive; their elements are real and can be pointed to. But constructs are hypothetical and more obviously theory dependent. Moreover, the formal methods statisticians prefer when sampling elements from a population cannot be used with constructs, because the necessary enumeration and sampling of elements cannot be readily achieved with measures of abstract constructs. This is why Cook and Campbell (1979) used external validity to refer to people and settings and construct validity to refer to instances of more hypothetical causes and effects. However, the distinction is partly arbitrary. Constructs have constitutive elements theoretically specified as their components, and instances of any one construct vary in which components they incorporate. Moreover, human populations are not totally ostensive per se. Despite official definitions, there is still room to disagree about what being an Australian means: what about someone with an Australian passport who has always lived abroad, or the illegal immigrant who has always lived in Australia without a passport? There is room for legitimate debate about the definition of any human class and about whether certain individuals fit within that class. Also, whether human populations or abstract constructs are involved, the functional task is always the same: justifying inferences from particular cases to general categories. Hence, we see no fundamental reason for treating populations and constructs differently, though we do respect social science terminology and often use the one to refer to people and settings and the other to cause and effect variables as well as causal moderators.

Formal Sampling Theory

The best way to represent a population is to enumerate its members before selecting a random sample from that population. When properly implemented, this guarantees that the sample will formally represent the population within known limits of sampling error. The sample and population distributions will match on all measured and unmeasured attributes. This makes random sampling the centerpiece of survey research, often complemented by other sampling details. To reduce costs, cases can be clustered within a geographic area before being randomly selected. To ensure that subpopulations are reliably represented, stratification can also occur before random selection. Formal sampling theory provides an impeccable justification for generalization to well-designated populations. And methods for implementing are now so improved that its use in describing human populations and some settings is almost routine.

The problem with random selection is its own limited generality. It rarely applies to causes and other abstract constructs (or to time). One cannot readily imagine enumerating all instances of a specific causal agent before selecting a random sample of these instances for study. In practice, causal agents are purposively chosen because of a presumed correspondence between substantive theory and operational instance(s). Likewise, it is rare for all possible measures of a construct to be enumerated before some are randomly chosen. The selection of measures to represent a construct is again purposive. Also, it is hardly practical to sample historical periods at random for generalizing, if not to eternity, then at least to some meaningful interval. Detailed measures are not always available from the past; and anyway, many theories predict temporal contingency rather than constancy. This last justifies the purposive selection of time periods for the unique light each throws on some causal process.

Even when selection is at random, unambiguous inference still depends on large samples that are not always readily forthcoming. How often can we randomly sample 50 or 100 time points for assessment? Or 50 or 100 institutions, unless the aim is to describe a particular class of institutions? What about manipulating causal agents within institutions? What proportion of those asked to participate will agree to do so? What types are these volunteer organizations likely to be – the most typical or the most proud?

Random sampling rarely applies to assessing the conditions under which cause and effect are related. We know of only six experiments where individuals or households were randomly selected before being randomly assigned to a treatment (see Shadish et al., 2001). However, survey researchers often use random sampling to test causal hypotheses, using item responses to identify variation in a possible causal agent and to provide outcome data. But this is widely acknowledged to generate inferior causal conclusions compared to experimenter-controlled intervention. So how can causal relationships be better generalized via the random selection that surveys afford if these relationships are more uncertain because a survey was used? Moreover, surveys do not routinely use random selection for other generalization-relevant features of the research. For instance, data are typically collected at one or a few time points only, and then in one type of setting (usually the home).

Random selection was not developed for extrapolation, generalizing beyond the sampling particulars. So, it is not surprising that it is not relevant to this function. Indeed, none of the extrapolation methods we later detail depends on random sampling. Other premises are involved, as they are for generalizing causal relationships and for selecting measures to represent constructs. Thanks to its logical and empirical warrant, random selection is *the* method of choice for generalizing to populations of persons and sometimes settings. But it is rarely relevant to other tasks with which a comprehensive theory of generalization must struggle.

Purposive Selection and Construct Validity

Purposive samples are selected without randomization and require only that the selected cases have certain prespecified characteristics. If these characteristics coincide with those of a population, then a match is achieved between the details in the population description and the details achieved in the sampling particulars. Unfortunately, such proximal matching cannot guarantee that the cases and categories are matched on all unmeasured characteristics, let alone perfectly matched on the measured ones. Purposive selection is less well theoretically justified than random selection. By itself, it justifies claims about category membership but not category representativeness.

Yet purposive selection is used throughout the social sciences. Even passionate advocates of random sampling measure behavior by first describing the construct to be assessed and then ensuring that measures of it include all attributes in the theoretical description. Empirical pattern matching between constructs and measures is the basis for generalization in this case, and substantive theory provides the template for choosing how to measure (or manipulate). The correspondence between construct and operational representation is usually multidimensional, with the most important attributes being the prototypical ones that most clearly define the construct's uniqueness (Brunswik, 1956).

Such pattern matching (also called proximal similarity) is not restricted to measurement contexts. When random selection is infeasible it also applies to selecting persons, settings, and times. Thus, experimenters might partition their data into gender subgroups. The resulting subsamples clearly correspond to the categories 'male' and 'female,' as inferred from body shape or valid self-reports. Selecting this way ensures a proximal similarity between the class 'female' and the sampled instances of that class. But do they represent their gender if all attend the University of Berlin? In such a case, the gender specifics and the construct match on some prototypical attributes; but the sample is much more internally homogeneous than the population with respect to age, intelligence, geography, and culture, among other factors. Belonging in a class does not entail formally representing that class. Proximal similarity is necessary but not sufficient for inferring the representativeness of sampled instances. Sophisticated construct validation requires more.

One auxiliary principle concerns 'the heterogeneity of irrelevancies' (Campbell, 1988), ensuring that the sample is not homogeneous on attributes that are irrelevant to the inference being made – such as age, intelligence, and nation in the case of females students in Berlin. To make these conceptual irrelevancies heterogeneous requires adding samples of women of different ages, social classes, and countries. In measurement contexts, heterogeneity requires multiple measures of each construct or varying multiple instances of a treatment, provided that each instance has unique irrelevancies and that no irrelevancy is shared by all instances. It also requires testing the degree of triangulation achieved across the sources of presumed irrelevancy.

Another way to deal with homogeneous irrelevancies requires focused comparison. If female students in Berlin are compared with their male counterparts, this holds constant irrelevancies like country, language, and city of testing, while also varying gender. But such internal comparisons are not always feasible; and groups may differ in other unmeasured irrelevancies that affect responding – e.g., if female students in Berlin have higher intelligence than males on the average, or if data collection there occurs in chemistry classes that attract different kinds of females than males. Whatever the construct being targeted – gender, intelligence, or being Australian – purposive sampling requires critically examining whether the instances selected are more homogeneous than their presumed population.

Construct validation also requires 'discriminant validity' (Campbell and Fiske, 1959), demonstrating that a relationship obtained with constructs labeled one way is not due to another construct that is correlated but nonetheless conceptually unique constructs. Thus, the validity of an anxiety measure requires not only showing that its measured attributes behave as hypothesized but also that they, as a whole, behave differently from conceptually related concepts like depression. Likewise, testing a hypothesis about how new computer firms are unique requires sampling more than just this type of firm. Also needed are firms making new products in other sectors. Relationships that hold across sectors can be generalized to firms in general, including computer firms. However, only relationships limited to computer firms help define what is unique about computer firms.

All sophisticated construct validity is about testing unique predictions entailed by the substantive theory of a population. We always validate interpretations of categories rather than categories themselves, even with human populations (Cronbach, 1989). Lawyers might pronounce that an Australian is anyone eligible for an Australian passport. But this definition is not adamantine. It includes individuals with Australian parents who have never lived in the country; it excludes illegal immigrants who have lived there for decades; and what about persons eligible for a passport who deliberately choose not to claim one despite living in the country for decades? No specification of a construct or population is beyond reasonable criticism and so each preferred interpretation must be defended. Usually, the interpretation can be formulated as hypotheses about some combination of components, antecedents, consequences, or correlates. Construct validation requires specifying and testing the nearest to unique of these hypotheses. Only then can we be truly confident about generalizing from purposive samples and measures to their target constructs rather than to some other entity correlated with them. However, constructing the arguments needed is more laborious and uncertainty-riddled than random sampling. Still, most social scientists sample purposively most of the time, though they vary greatly in how much auxiliary information they collect after a modicum of proximal similarity has been achieved.

Generalizing Causal Connections

Much effort goes into testing causal hypotheses – statements that variation in one construct leads to variation in another and that no alternative cause can account for their covariation. Generalizing causal statements depends on methods other

than formal sampling theory, given that experiments with both random selection and random assignment are rare and surveys provide causal tests that are flawed when compared to experiments. So, how is generalization achieved when the object to be generalized is a causal claim?

One way is when a population has recently been described using measures that are also available on a purposive sample of persons or sites. Then, any causal relationships obtained at the sample level can be weighted to the population level, using the empirical relationship between sample and population for this purpose. But such weighting only approximates what the population effect size would have been if the sample had been randomly selected. Correct inference depends on the sample level effect sizes not being affected by unmeasured sample characteristics that are not fully captured by the shared, measured variables. Still, we can anticipate that weighting procedures will be used more often in the future as methods for social experiments and estimating missing data advance. After all, survey researchers now describe human populations from biased sample data using basically the same weighting technique.

Sometimes, substantive theory is specific enough to detail the conditions under which a causal relationship holds. Then, a program of research can test explicit hypotheses about specific sources of population, setting, or time variation in the strength or direction of the causal relationship. This involves deliberate attempts to falsify the hypothesis that a causal connection is general (Gadenne, 1976). Rejecting the hypothesis entails identifying specific causal moderators; failure to reject implies that the hypothesis of a general cause–effect relationship remains viable. A less formal variant of this describes common practice in the laboratory sciences. A causal claim is made and then independently replicated, often under conditions that approximate the original ones. Successful replication leads to concluding that the causal relationship is provisionally true – that is, true until future failures to replicate indicate the need to invoke causal moderator variables. In both approaches, special emphasis is on identifying moderators that reduce the causal relationship to zero or that change its sign, as opposed to those that merely vary its size without affecting its sign.

Purposive sampling is also used in other less formal generalization probes. In clinical trials, hospitals recruit patients with a given disease and then adhere to the study's intervention and data collection protocols. Hospitals are basically chosen for their willingness to comply and for their heterogeneity with respect to, say, region of the country, predominant ethnic group served, or type of hospital sponsorship. Statistical power is often only adequate for cross-site analysis, suggesting that the goal is not to identify site-level main and interaction effects, but to see if the causal estimate exceeds zero despite heterogeneity in the hospitals studied. If it does, the causal effect is held to be general. If it does not, several alternative claims are viable and need to be tested, especially the following: there is no effect; the causal sign varies by hospital type and obscures a main effect; or the methods used cannot detect an effect of the size expected. Only increasing the sample of sites allows direct tests of which hospital types are involved in site-level interactions. Even so, relying on a purposive sample of sites that are heterogeneous on many attributes except for volunteering is only logically defensible if researchers know from other sources that no confounds are associated with all the hospitals being volunteers for the clinical trial.

Exploratory analyses often involve measuring many constructs from among a large array of possible causal modifiers in order to probe which ones affect the strength of a causal relationship. Without a priori hypotheses about modifiers, the approach can be time-consuming and run afoul of error rate problems due to the many tests conducted and the small sample sizes for some values on the moderator. Nonetheless, subcategory breakdowns are often used within experiments to probe how robust a relationship is across persons, settings, times, and measures. This can prevent the overgeneralization that occurs when researchers conclude that a relationship found with the entire sample holds in each subgroup within the sample. The entire sample allows one to conclude that the effect is found despite the internal heterogeneity achieved. It does not imply there is independent replication within any of the individual subgroups. The story is essentially the same when partitioning data from a single survey. With adequate sample sizes per group, one can probe the robustness of a relationship across the subgroups sampled. But only those potential conditional variables directly sampled can be assessed.

The best tests of causal conditionals come from synthesizing multiple studies on a topic rather than from subgroup breakdowns within a single study (Cooper and Hedges, 1994). Experiments and surveys relevant to the same causal hypothesis accumulate and can be used in meta-analysis, the best-known form of synthesis. Meta-analysis combines data across multiple studies asking the same question, taking advantage of the between-study variation in measures, manipulations, populations of people, settings, and times. The dependent variable is each study's standardized effect size(s) and these are manipulated (1) to generate an average effect size across all the studies and all the irrelevant sources of heterogeneity they contain, and (2) to identify the specific contingency factors responsible for variation in the effect sizes.

What logic buttresses meta-analysis? It is not random sampling since individual studies are selected for their relevance to the hypothesis and the hope is to achieve a census of all published and unpublished studies. However, the more relevant target population is all studies that could be conducted on the topic, not all those done on it. In meta-analytic practice, generalization depends on the sample of achieved studies including a wide range of human populations, setting types, historical periods, and operationalizations of the cause and effect. Each study is first coded to label its sampling particulars in terms of theoretical constructs and to examine the sources of irrelevancy with which the particulars are and are not collectively imbued. Thus in a hospital experiment, hospitals might be described as being university-based, public, or private, and as being large or small. Patients might be described in terms of diagnosis, age and gender mix, etc. The treatment might be described in terms of its components, duration, and manner of delivery; and the outcome might be described in similar terms. Then researchers typically test whether the same causal relationship holds despite these sources of sampled irrelevancy.

Sample sizes permitting, researchers also test whether the relationship holds across individually identified sources of

potential irrelevancy so as to generalize to hospitals in general, people diagnosed with cancer, or whatever the target inferences might be for a particular study. Important here are the number and especially the heterogeneity of the types examined. Of course, some sources of variation might have a priori substantive meaning, as when university hospitals are a special target. Then one has to do a discriminant validity test and show that the effect size for such hospitals is different from that for other hospitals. Otherwise, there is nothing unique about university hospitals. So, meta-analysis depends on the very tests for proximal similarity, heterogeneous irrelevancy, and discriminant validity that are so central in construct validation. In addition, to achieve such tests multiple replication is needed across studies that may each be individually very narrow in the range of people, settings, times, and cause and effect operations it includes. Central is the heterogeneity across studies and the pattern of results achieved despite this sampled heterogeneity.

Extrapolating to Nonsampled Entities

Some social scientists probably think it silly to use samples for generalizing to populations that are not even proximally similar to the samples used. So, many animal researchers abjure all talk of generalizing to humans. But their language is often anthropomorphic, and their research is usually funded because others think it is relevant to humans. So, elaborate reasoning has evolved over time to justify generalizing from animals to humans (Steel, 2008).

In this regard, consider the use of cats in visual research (Blake, 1988). The rationale for their use is in two parts. The first is entirely pragmatic and stresses the conveniences of working with cats (or *Drosophila* in genetics research), usually because of cost and ethics. The second is theoretical and is based both on cats sharing some anatomical and physiological features with humans and on behavioral research showing that cats and humans behave similarly when confronted with similar visual stimuli. However, the empirical work necessary for showing such correspondences has also revealed that cats are much less like humans in some physical ways – especially features related to night vision – and that some behaviors are not replicated across species when the same stimulus is presented. So, a contingency theory has evolved of the conditions under which cats are better or worse substitutes for humans.

But when asked, honest vision researchers will avow that convenience is the paramount rationale for using cats. Would they rather work with chimpanzees? Undoubtedly, since the chimps' visual system is much closer to humans' than the cats.' But the expense of maintaining chimps precludes using them. Would the researchers rather use humans than chimps? Undoubtedly, if ethical research procedures are possible – which they often are not. However, now that new imaging technologies are available that allow observing the human eye reacting to planned stimuli in great microdetail and real time, many vision researchers are turning to work with humans rather than cats because the pragmatic obstacles to using humans now hardly apply. Thus within the community of vision researchers the preference for generalization to humans via within-species proximal similarity is clear. So, too, is the distaste for arguments that depend on the (only partial) proximal similarity between cat and human on some vision-related attributes given their obvious dissimilarity in others. A similar story could be told for conducting research in the laboratory rather than in the field (Shadish and Cook, 2009). Convenience is paramount, and the reasons given for preferring the lab often contain elements of rationalization. But even so, extrapolation across species and settings is surely superior when there is an empirically defensible contingency theory of the conditions under which the extrapolation is better and worse warranted.

How is extrapolation otherwise achieved? Causal explanation is often held to play a major role, explaining how or why two or more things are related (Mackie, 1974). Once an explanatory process has been identified, the argument is that it can be reproduced in other settings, with other kinds of people, at future times, and with unique ways of instantiating the process. Indeed, this is the major public rationale for basic science. Once one knows why fire happens, one can replicate it with new kinds of materials (say, some newly invented polymers), in new settings (an uninhabited desert island), and with people who have never seen fire before (so long as they can understand the explanatory recipe). The problem with this view is that full explanation is hard to conceptualize and achieve. It is difficult enough to use data for discriminating among explanatory claims even at one level of explanation, let alone for simultaneously investigating factors at the biological, individual, and social levels. Even so, causal explanation is the holy grail of science, not just for its aesthetic parsimony, but also for the utilitarian causal generalization it promotes in the form of extrapolation.

Extrapolation is also achieved through careful induction. If patient education reduces the length of hospital stays and does so with patients suffering from 25 different diagnoses, then it is likely to do so with the 26th. Of course, the logical warrant for such induction is limited, and seems more reasonable the more numerous and heterogeneous are the patient types already examined. If all 25 were different forms of cancer diagnosis, or involved patients aged between 25 and 40, or were restricted to men, this limited heterogeneity would reduce our confidence in any inductive-empirical extrapolation. Meta-analysis is particularly important in this regard, especially when it permits replication across multiple different sources of irrelevancy. A relationship that has proven to be robust in whatever form it was operationalized is more likely to reoccur when other ways of operationalizing its components are attempted – more likely, but not certain. We see here the value traditionally assigned in science to discovering both general dependencies and the contingencies that describe when a given relationship does and does not hold.

The final context for extrapolation relates to formal modeling. When subgroups can be arrayed along a single continuum, the functional form of a causal relationship can then be described. Is it stable? Is there a linear increase or decrease? If a pattern clearly emerges, one might want to argue that the strength of the relationship can be inferred for unobserved subpopulations with values that fall within the continuum range. Simple interpolation is involved here, while the strength of the relationship for values beyond the continuum is inferred by extrapolating from the observed function. But comfort with such extrapolation depends on how

distant the nonobserved subpopulation values are from the sampled ones.
